INFORMATION TO USERS

This material was produced from a microfilm copy of the original document. While the most advanced technological means to photograph and reproduce this document have been used, the quality is heavily dependent upon the quality of the original submitted.

The following explanation of techniques is provided to help you understand markings or patterns which may appear on this reproduction.

1. The sign or "target" for pages apparently lacking from the document photographed is "Missing Page(s)". If it was possible to obtain the missing page(s) or section, they are spliced into the film along with adjacent pages. This may have necessitated cutting thru an image and duplicating adjacent pages to insure you complete continuity.

2. When an image on the film is obliterated with a large round black mark, it is an indication that the photographer suspected that the copy may have moved during exposure and thus cause a blurred image. You will find a good image of the page in the adjacent frame.

3. When a map, drawing or chart, etc., was part of the material being photographed the photographer followed a definite method in "sectioning" the material. It is customary to begin photoing at the upper left hand corner of a large sheet and to continue photoing from left to right in equal sections with a small overlap. If necessary, sectioning is continued again — beginning below the first row and continuing on until complete.

4. The majority of users indicate that the textual content is of greatest value, however, a somewhat higher quality reproduction could be made from "photographs" if essential to the understanding of the dissertation. Silver prints of "photographs" may be ordered at additional charge by writing the Order Department, giving the catalog number, title, author and specific pages you wish reproduced.

5. PLEASE NOTE: Some pages may have indistinct print. Filmed as received.

DISSERTATION COMMITTEE

ABSTRACT

The invariant imbedding neutron transport equations were studied by the iterative Lie series perturbation method, taking the first three terms of a Taylor series expansion as the solutions to the perturbed system, which has the same initial condition as the given equations, and using it as a starting solution in the iteration method. Three terms of the Lie series expansion were used in each process as a correction.

The principal result from this investigation is that the iterative Lie series perturbation method is effective in solving the invariant imbedding transport equations. Numerical results obtained for the reflection function of a semi-infinite homogeneous slab were in excellent agreement with those by the Runge-Kutta method given by Bellman. The local truncation errors in the calculations were below 10^{-12}. Furthermore, because of fast convergence, the higher orders of the method are not necessary to yield accurate results. Also, with the variable step size controls, decreases in rounding errors are expected in comparison with the fixed step size calculations.

From indirect comparison, the iterative Lie series perturbation method is faster than the Runge-Kutta method.

ACKNOWLEDGMENTS

The author desires to express his sincere gratitude to his research advisor, Dr. John C. Zink, for his incessant guidance and interest; to the members of his Doctoral Advisory Committee: Dr. Maurice L. Rasmussen, Dr. James A. Payne, Dr. David W. Anderson, and Dr. James B. Freim for their invaluable suggestions and advices; To Dr. Tom J. Love Jr., and Dr. David M. Elliott for their initially serving in the committee.

The author is also like to extend his sincere appreciation to the University of Oklahoma for the graduate assistantship during his stay in the School of Aerospace, Mechanical and Nuclear Engineering; to the Computer Center of the University of Oklahoma, for the use of the facility as well as for their assistance.

This work could not have been completed without all their support.

LIE SERIES SOLUTION OF INVARIANT IMBEDDING NEUTRON TRANSPORT EQUATIONS

CHAPTER I

INTRODUCTION

Neutron transport theory is concerned with the neutron flux distribution as a function of position, velocity, and time in the medium. The engineers' interest in neutron transport theory is in the study and design of nuclear reactors, such as their radiation shielding and reactor criticality calculations. The methods developed in neutron transport theory can be applied to other transport problems in engineering and physics, such as the study of wave propagation, electron motion in plasmas, electron discharge, penetration of gamma rays through scattering media, radiative transfer in stellar atmosphere[1], etc.

The invariant imbedding formulation of the equations in engineering and the physical sciences, including neutron transport has been developed during the past fifteen years with a goal of achieving a formulation more suitable for application of a digital computer. The reason for this is that the invariant imbedding formulation of the equation is a non-linear initial value problem, which can be solved relatively simply. But in the classical approach, the result is a boundary value problem, which requires at some stage the solution of a large system of linear equations[2].

There is another advantage of invariant imbedding approach over the

classical Boltzmann approach. For the invariant imbedding approach, an extension to a slab of large thickness is easy; the transmission function for a thickness 2X can be obtained readily from the function for a thickness X by utilizing the functional relationship [3].

The essence of the invariant imbedding concept is to imbed a particular problem in a family of problems. The family provides a means of advancing gradually from the solution for one member to the solution of the total problem.

The mathematical tool we employed here to solve the invariant imbedding transport equations is a Lie series method. The Lie series is a special power series containing differential operators. It is named after Sophus Lie, a Norwegian mathematician, and was introduced by Wolfgang Gröbner [4], Innsbruck University, Austria, in the early 60's to solve special problems in algebraic geometry.

The possibility of solving differential equations by power series expansions has been known since B. Taylor (1685-1731) first undertook this work. As a practical computational scheme this approach has been deemed infeasible because of the task of deriving expressions for higher derivatives. On the other hand, series methods can give results of arbitrarily high accuracy, provided that the series converges, and that a sufficient amount of time is expended on their calculation. Good numerical results obtained by Taylor series expansions have been reported for certain differential equations [5-6].

Due to the impact of modern high speed digital computers, the calculation of higher derivatives in the series expansion is no longer a problem. Thus, the feasibility of studying the differential equations by the series method is coming to the fore.

CHAPTER II

RESEARCH OBJECTIVES

The primary objective of this work is to show that the Lie series method is suitable for solving invariant imbedding transport equations. It is also to be shown that accuracy is maintained and that savings in computer time are realized.

There are four variable parameters encountered in applying the iterative Lie series perturbation method to a problem: one can choose from several approximations (for example, the number of terms in the Taylor series expansion) to the solution of the perturbed system, its initial conditions are the same as the given equations; number of terms used in the Lie series expansion, in each iterative process, as correction; local error bound used in the step size control; and the number of nodes in the Gaussian quadrature formula used to approximate the integrations.

A secondary objective is, then, to study the effects of these parameters on the precision of the results, and on the computing time required.

CHAPTER III

LITERATURE SURVEY

When a neutron balance equation is written for any region of a reactor core, we get the classical starting point of neutron transport theory, the Boltzmann transport equation. The most comprehensive work in this area is probably the book of Davison and Sykes[7]; other notable publications are by Kourganoff[8], and by Case and Zweifel[9]. However, by reviewing some relatively new theoretical efforts as well as the new development of the old ideas which arose from other fields, the basis of neutron transport theory has been broadened. The following is the summary of the recent (from mid 50's to date) developments in neutron transport theory, with emphasis on the invariant imbedding concept.

1. Quantum mechanical approach. The most fundamental of this type approach has been the works of Osborn and Yip[10], and of Jauho and Riska[11]. They gave conditions for the validity of the transport equation: the side of a cube of the smallest region of validity is $\Lambda >> 10^{-4}$ cm., and the energies of the neutron must be $>> 10^{-3}$ mev. To date the quantum mechanical transport theory has not been used to obtain any results which are not more simply found from classical theory.

2. Stochastic transport theory. Neutron transport theory is ordinarily concerned with the mean or expected value of a neutron density. The actual neutron density in a system may or may not resemble the mean value of the density. Generally speaking, if there are few neutrons in a system, the actual density at certain time within certain region of the system is

unlikely to resemble the mean density of the system. But if there are many neutrons in a system, the actual density for a certain region of the system is likely to be very similar to the expected one.

These two extreme examples typify the two most important types of practical questions which have motivated the development of a stochastic theory of neutron transport.

In formulating the transport equations, we generally treat the function as continuous in space, velocity, and time. But it is more fruitful in the stochastic process to treat neutrons a generation at a time. It appears that there are mathematical advantages in doing so. The neutrons in successive generations are simply related and their probability generating functions are connected by a transformation which can be studied.

There are several people working on this area: notably, Pal[12], who in 1958 published the theory of stochastic processes in nuclear reactors. He framed his theory in terms of the probability that a single neutron would lead to "n" neutrons at a later time. By considering the various possible first collisions, and introducing the generating function, he derived the nonlinear integrodifferential equation satisfied by the generating function. Because of ignorance of the space and energy dependence in his theory, it ends up as a point reactor model.

In 1965, Bell[13] clarified the relationship of the extinction probability to the generating function, and in 1966 Otsuka and Saito[14] elucidated the relationship between generating functions and product densities of all orders.

Abu-Shumays[15] uses the generating functions to treat the one energy group transport problem for slab geometry with axial symmetry and constant

cross-section. Numerical results for reflection and transmission functions were carried out based on the X- and Y-functions of Chandrasekhar.

Also in 1966, the Langevin's equation was introduced by Sheff and Akcasu[16]. It borrows from the Langevin theory of Brownian motion. In this form of transport theory it is postulated that the difference between the actual neutron density and the mean one is maintained by a random source which arises from the fluctuations in neutron density itself. The physical basis of the Langevin approach seems less rigorous than the first two.

3. Invariant imbedding approach. The invariant imbedding, or the method of continuity, is a fundamental technique of mathematics [17]. It stems from the principle of invariance, introduced by Ambarzumian[18] in astrophysics in 1943, and was extended to radiative transfer by Chandrasekhar [19] in about 1950. After 1956[20-31], through the efforts of Bellman and his colleagues, it found a wide application in radiative transfer[19][33-41], neutron transport [3][35][42-75], random walk and scattering [3][76-82], wave propagation[83-85], rarefied gas dynamics [86-87], Hamilton's equation of motion[88], nonlinear filtering theory[89], quantum mechanics[90], and solid state physics[91]. In short, the invariant imbedding concept is applicable to the treatment of boundary value problems [92-106] and eigenvalue problems[107-108].

The invariant imbedding equations can be obtained from an analysis of the original physical process (in transport theory it is called the "particle counting" technique), which we will employ in the next section, or from the classical equations representing the process [21][26][29][44] [93-104]. Wing[73] illustrated that the reflection equations derived from the classical method and those from invariant imbedding are equivalent.

The "particle counting" technique is fairly prone to error for cylindrical and spherical geometries[43]. However, it does provide a clear picture of the processes.

Although the bulk of papers deal with invariant imbedding formulation of the transport equation, and little work has been done actually on the methods of solution, the problem of deriving invariant imbedding equations for internal flux[53-55][65][70], anisotropic scattering[78a], etc. are still under investigation.

Thus, there are two ways we can approach the study of transport theory: one is from the analytical aspect, the other is from the numerical aspect. From the analytical aspect, one deals with the formulation of the equations and proof for the existence and uniqueness of the solutions. From the numerical aspect, our goal is to find an efficient technique for obtaining numerical solutions on digital computers.

There are four numerical results which related to the invariant imbedding approach. In 1963, Bellman and his colleagues[2] solved the reflection equations for a one-dimensional slab; in 1966, Mathews[61] applied the invariant imbedding method to a shielding problem; in about the same time, Shimizu[3] applied the invariant imbedding method to the reflection and transmission problem of gamma rays. In 1970, Zink[75] extended the method to the two-dimensional slab problem for both reflection and transmission functions.

In the four above cases the Gaussian quadrature formula were used in performing the integrations with respect to the angular variable. Bellman, Mathews, and Zink used the Runge-Kutta method in the numerical calculations. Mathews also tried the Adams method, which was faster

than the Runge-Kutta method and gave a relatively easy estimate of truncation error per step, but was discarded because of problems with numerical instability and because of the large amount of computer memory storage required. The Runge-Kutta method was easy to apply, but it was very time consuming, and it also lacked an easy method of estimating the local truncation error. Shimizu used the iteration method, starting from the first order first degree solutions by neglecting the second degree terms in the equations. Solutions of adequate accuracy was obtained upon two to ten iterations.

Numerical results for the one-dimensional monoenergetic reflection function were found within one to two percent of those that obtained from Chandrasekhar's X- and Y-function[19][109]. For the two dimensional case it was found that the results were smaller than those of a one-dimensional slab because of the leakage from the sides. The theoretical results of Shimizu's calculation of the energy and angular distribution of transmitted photons were compared with experiments and found to be in good agreement.

CHAPTER IV

FORMULATION OF THE THEORY

4.1 Hypotheses

The most important assumptions made in derivation of the transport equations are:

1. The neutron is a point particle, moving at speed c, characterized only by its position and direction of motion.

2. The moving neutrons may collide only with the fixed nuclei of the medium; interaction between the moving neutrons will not be considered.

3. A collision always results in the disappearance of the original neutron and the appearance of "γ" new neutrons at the point of collision. These are emitted isotropically and intantaneously.

4. No more than a single collision is assumed.

5. No internal source.

The assumptions made in solving the transport equations are:

1. The transport functions are continuous, and satisfy a Lipschitz condition, so that the solutions exist and are unique.

2. The transport functions are sufficiently differentiable, so that all the terms in Taylor series and Lie series exist.

4.2 Formulation of the Reflection Equations

In the following derivation of the transport equations, a new graphical representation of collision process was introduced. The one-dimensional invariant imbedding reflection equation was first formulated by Bellman[2], and explained partly due to Wing[73]. The two-dimensional

equation was introduced by Zink[75]. In this Chapter clarifications were made on both one- and two-dimensional equations.

4.2 One dimensional reflection function

Consider an input of one particle per second per unit area of a slab surface, and moving in the direction Ω_0.

The probability of one of the injected particles having a collision in passing from $x+\Delta$ to x (Fig. 1, top) is

$$p_2^0 = \sigma(x)\frac{\Delta}{|\mu_0|}$$

where $\sigma(x)$ is the probability of collision per unit path length, and μ_0 is the cosine of angle θ_0. The expected flux thus produced in direction Ω is

$$R_a = p_2^0 k(x,\Omega,\Omega_0),$$

where k is the expected number of secondaries per cm^2 per second going in direction Ω as a result of a collision at x, due to a unit incident flux in direction Ω_0. This process is symbolically represented by R_a in Fig. 1.

Now, consider an injected particle having a collision in $(x,x+\Delta)$ and giving rise to particle going in direction Ω'', where $\frac{1}{2}\pi \leq \theta'' \leq \pi$, and θ'' is the polar-angle component of Ω''. The number of such particles impinging per second on a unit area perpendicular to the outward normal $\bar{n}$ at x and moving in direction Ω'' is

$$p_2^0 k(x,\Omega'',\Omega_0).$$

This amount of flux at x produces a neutron density at $x+\Delta$, moving in direction Ω, due to reflection, of

$$p_2^0 k(x,\Omega'',\Omega_0) R(x,\Omega,\Omega'')(1-p_2),$$

and thus contributes to a flux (moving in direction Ω) normal to $\bar{n}$ of

$$R_b = p_2^0 kc\mu \int_0^{2\pi}\int_{-1}^{0} R(x,\Omega,\Omega'')d\mu''d\phi'' + o(\Delta),$$

where c is the speed of neutron. $R(x,\Omega,\Omega'')$ is called the reflection function, and it has unit of density [#/cm^3]. This result is shown by R_b in Fig. 1, where $p_1' = 1 - p_2^0$ is the probability of suffering no collision in traversing a distance Δ/μ_0. The term involving $p_2^0 p_2$ is small in comparsion with p_2^0 and thus is represented here by $o(\Delta)$.

Here we also assume the collision process is isotropic, so that k is independent of Ω and x. Thus,

$$\int_\Omega k d\Omega = \gamma,$$

or $$k = \gamma/4\pi,$$

where γ is the total expected number of secondaries per collision.

Continuing this kind of analysis we will obtain the expressions for R_c, R_d, and R_e respectively.

All other processes involve two or more collisions in $(x,x+\Delta)$ and only contribute a term $o(\Delta)$ to those already included.

By combining five processes in Fig. 1, we get the flux at $x+\Delta$ which is normal to the slab and moving in direction Ω,

$$c\mu R(x+\Delta,\mu,\mu_0) = R_a + R_b + R_c + R_d + R_e.$$

Let $c\mu R(x,\mu,\mu_0) = \hat{R}(x,\mu,\mu_0)$.

Then, $$\lim_{\Delta\to 0} \frac{\hat{R}(x+\Delta,\mu,\mu_0)}{\Delta} = \frac{\partial \hat{R}(x,\mu,\mu_0)}{\partial x}$$

$$= \sigma\gamma/4\pi|\mu_0| + \sigma\gamma/4\pi|\mu_0| \cdot \int_0^{2\pi} d\phi'' \int_0^1 \hat{R}(x,\mu,\phi;\mu'',\phi'')d\mu''$$

$$- \hat{R}(x,\mu,\phi;\mu_0,\phi_0)\left[\frac{1}{|\mu_0|} + \frac{1}{\mu}\right]$$

$$+ \frac{\sigma\gamma}{4\pi}\int_0^{2\pi} d\phi' \int_0^1 \hat{R}(x,\mu',\phi';\mu_0,\phi_0)\frac{d\mu'}{\mu'} \qquad (4\text{-}1)$$

$$+ \frac{\sigma\gamma}{4\pi}\int_0^{2\pi} d\phi \int_0^1 \hat{R}(x,\mu',\phi';\mu_0,\phi_0)\frac{d\mu'}{\mu'}\int_0^{2\pi} d\phi'' \int_0^1 \hat{R}(x,\mu,\phi;\mu'',\phi'')d\mu'',$$

with the initial condition that

$$\hat{R}(0,\mu,\phi;\mu_0,\phi_0) = 0. \qquad (4\text{-}2)$$

The purpose of introducing $\hat{R}$ is to change the function R, which is odd in its argument, μ, to an even function. Thus we can confine the domain of angular variables μ to (0,1), and simplify the transport equation.

By substituting

$$r(x,\mu,\phi;\mu_0,\phi_0) = 4\pi\mu_0\hat{R}(x,\mu,\phi;\mu_0,\phi_0)$$

into Eq.(4-1) and letting $\sigma = 1$ (unitary mean free path), Eq.(4-1) becomes

$$\frac{\partial r}{\partial x} + \left(\frac{1}{\mu_0} + \frac{1}{\mu}\right)r = \frac{1}{\gamma}\left[1 + \frac{1}{2}\int_0^1 r(x,\mu,\mu'')\frac{d\mu''}{\mu''}\right]$$

$$\times \left[1 + \frac{1}{2}\int_0^1 r(x,\mu',\mu_0)\frac{d\mu'}{\mu'}\right] \qquad (4\text{-}3)$$

with $r(0,\mu,\mu_0) = 0.$

We see that (4-3) is symmetric in its angular arguments.

4.3 Two-dimensional reflection functions

The physical model of the collision processes is shown in Fig. 2. From this one can determine the flux at angle Ω from the normal to the slab at position $(x+\Delta,y)$ due to the neutrons incident at $(x+\Delta,y_0)$ in direction Ω_0 at the rate of 1 per cm^2 per second. This can be written as:

$$c\mu R(x+\Delta,y,\Omega,\Omega_0) = R_a + R_b + R_c + R_d + R_e.$$

Let $c\mu R(x,y,\Omega,\Omega_0) = \hat{R}(x,y,\Omega,\Omega_0)$,

then, $$\lim_{\Delta\to 0}\frac{\hat{R}(x+\Delta,y,\Omega,\Omega_0)-\hat{R}(x,y,\Omega,\Omega_0)}{\Delta}=\frac{\partial\hat{R}}{\partial x}$$

$$=\frac{\gamma}{4\pi\mu_0}-\left(\frac{1}{\mu_0}+\frac{1}{\mu}\right)\hat{R}(x,y,\Omega,\Omega_0)$$

$$+\frac{\gamma}{4\pi\mu_0}\int_{\Omega''}\hat{R}(x,y,\Omega,\Omega'')d\Omega''$$

$$+\frac{\gamma}{4\pi}\int_{y'}\int_{\Omega'}\frac{\hat{R}(x,y',\Omega',\Omega_0)}{\mu'}d\Omega'dy'$$

$$+\frac{\gamma}{4\pi}\int_{\Omega''}\int_{y'}\int_{\Omega'}\frac{\hat{R}(x,y;\Omega',\Omega_0)}{\mu'}d\Omega'dy'\hat{R}(x,y,\Omega,\Omega'')d\Omega'', \qquad (4\text{-}5)$$

with the initial condition that

$$\hat{R}(0,y,\Omega,\Omega_0)=0. \qquad (4\text{-}6)$$

Although we assume that the collision process is isotropic, it does not mean that the reflected flux is azimuthally-symmetric. To simplify the equation, introduce a new function[75]

$$\bar{R}(x,y,\mu,\phi;\mu_0)=2\pi\int_0^{2\pi}\hat{R}(x,y,\Omega,\Omega_0)d\phi_0. \qquad (4\text{-}7)$$

Operating on (4-5) by $\int_0^{2\pi}d\phi_0\int_0^{2\pi}d\phi''$ and applying (4-7), we have

$$\frac{\partial\bar{R}}{\partial x}(x,y,\mu,\phi;\mu_0)=\frac{\gamma\pi}{\mu_0}-\left(\frac{1}{\mu_0}+\frac{1}{\mu}\right)\bar{R}(x,y,\mu,\phi;\mu_0)$$

$$+\frac{\gamma}{2\mu_0}\int_0^1\bar{R}(x,y,\mu,\phi;\mu'')d\mu''+\frac{\gamma}{4\pi}\int_0^1dy'\int_0^{2\pi}\int_0^1\frac{\bar{R}(x,y,\mu',\phi';\mu_0)}{\mu'}d\mu'd\phi'$$

$$+\frac{\gamma}{8\pi^2}\int_0^{2\pi}\int_0^1\int_0^1\int_0^1\frac{\bar{R}(x,y';\mu',\phi';\mu_0)\bar{R}(x,y,\mu,\phi;\mu'')}{\mu'}dy'd\mu''d\mu'd\phi', \qquad (4\text{-}8)$$

with the initial condition that

$$\bar{R}(0,y,\mu,\phi;\mu_0)=0. \qquad (4\text{-}9)$$

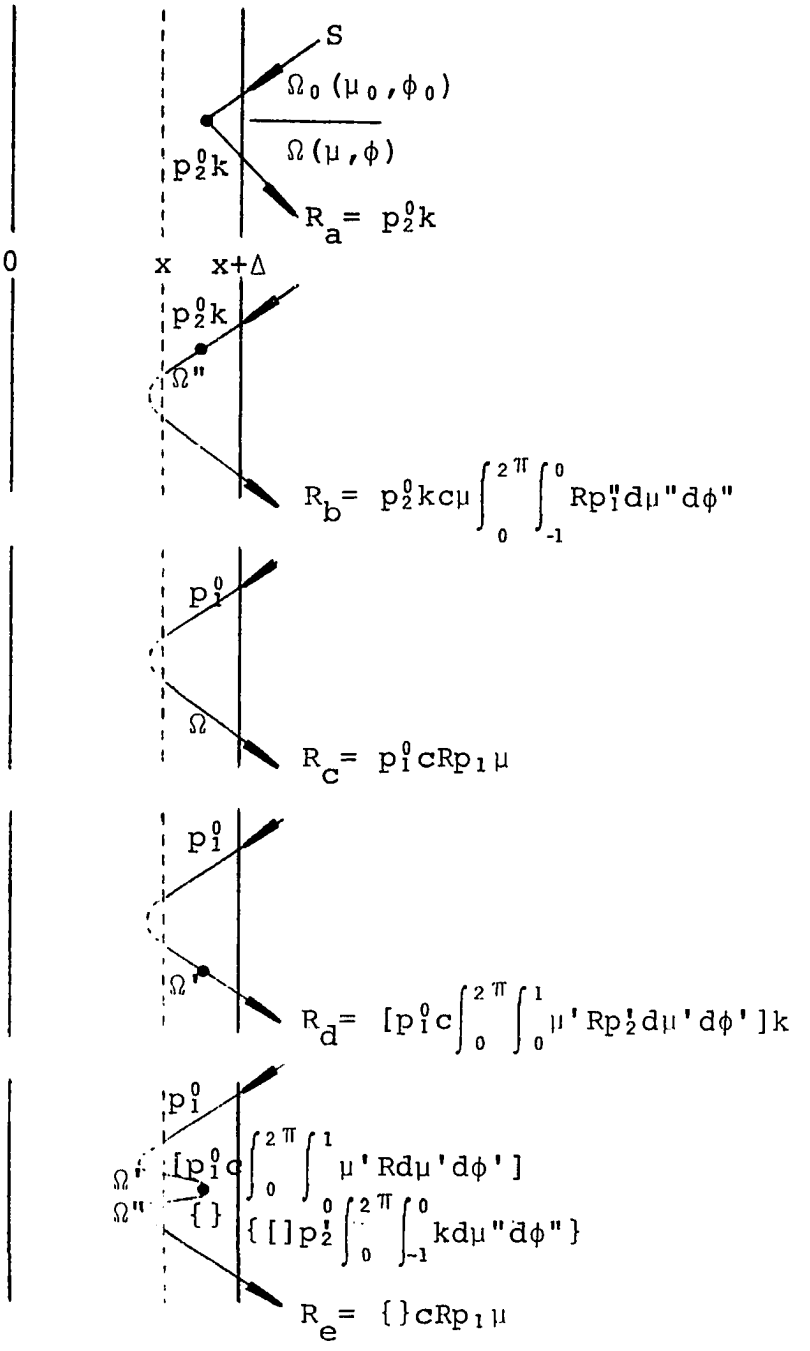

Fig. 1. The physical model of the collision processes.

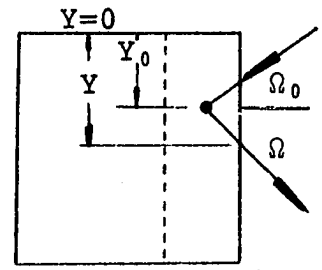
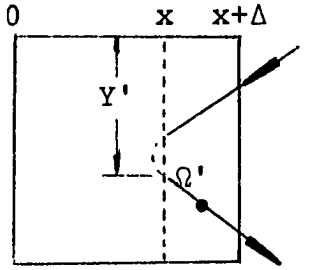
A dot indicates that a collision has taken place in (x, x+Δ). The normal components are represented by R_a, R_b,..., R_e.

The paths are dashed in (0,x) to emphasize the fact that the details of the particle behavior there are of no interest to us.

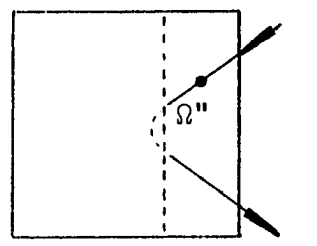


$$R_a = \frac{\sigma\Delta}{|\mu_0|}\,\frac{\gamma}{4\pi},$$



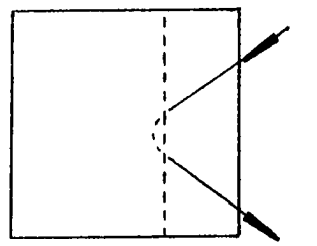
$$R_b = \int_{Y'}\int_{\Omega'} \left[1-\frac{\sigma\Delta}{|\mu_0|}\right] c\mu' R(x,Y';\Omega';\Omega_0)\,d\Omega'\,dY'\,\frac{\sigma\Delta\gamma}{\mu' 4\pi}$$

$$= \frac{\sigma\Delta\gamma}{4\pi}\int_{Y'}\int_{\Omega'} cR(x,Y';\Omega';\Omega_0)\,d\Omega'\,dY' + o(\Delta),$$



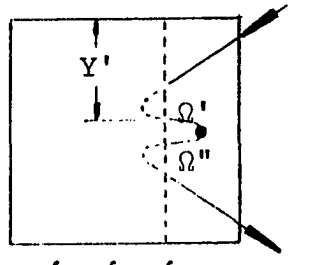
$$R_c = \frac{\sigma\Delta}{|\mu_0|}\,\frac{\gamma}{4\pi}\int_{\Omega"} c\mu R(x,Y,\Omega,\Omega")\,d\Omega"\left[1-\frac{\sigma\Delta}{\mu}\right]$$

$$= \frac{\sigma\Delta}{|\mu_0|}\,\frac{\gamma}{4\pi}\int_{\Omega"} c\mu R(x,Y,\Omega,\Omega")\,d\Omega" + o(\Delta),$$



$$R_d = \left[1-\frac{\sigma\Delta}{|\mu_0|}\right] c\mu R(x,Y,\Omega,\Omega_0)\left[1-\frac{\sigma\Delta}{\mu}\right]$$

$$= c\mu R(x,Y,\Omega,\Omega_0) - \sigma\Delta\left(\frac{1}{|\mu_0|}+\frac{1}{\mu}\right) c\mu R(x,Y,\Omega,\Omega_0) + o(\Delta),$$



R_e

$$R_e = \int_{\Omega"}\int_{Y'}\int_{\Omega'} \left[1-\frac{\sigma\Delta}{|\mu_0|}\right] c\mu' R(x,Y',\Omega';\Omega_0)\,\frac{\sigma\Delta\gamma}{4\pi\mu}\,c\mu R(x,Y,\Omega,\Omega")\,d\Omega'\,dY'\,d\Omega"$$

$$\times\left[1-\frac{\sigma\Delta}{\mu}\right].$$

Fig. 2. The physical model of the collision processes for a two-dimensional slab. o(Δ) represents higher-order terms, or terms involving powers of Δ higher than first.

CHAPTER V

LIE SERIES PERTURBATION METHOD

The development of the Lie series method are due to Gröbner, Knapp, Wanner et al.[110], of Innsbruck University, Austria. In this section we try to clarify some of their ideas, consolidate scattered materials into one piece, and to use them to solve the invariant imbedding transport equations.

5.1 Definition of the Lie series

Let $F(x,y)$ be an analytic or a sufficiently differentiable function of the variables $x, y_1, \ldots\ldots, y_n$.

Where

$$y = \begin{bmatrix} y_1 \\ \cdot \\ \cdot \\ y_n \end{bmatrix} \tag{5-1}$$

are solutions of a system of first order ordinary differential equations.

$$y_i' = f_i(x,y_1,\ldots, y_n). \qquad (i = 1,\ldots, n) \tag{5-2}$$

Inserting solutions $y_1(x),\ldots, y_n(x)$ in the place of $y_1,\ldots, y_n$ we find a function that depends on x only. By the chain rule, its derivative with respect to this variable is

$$\frac{d}{dx} F(x,y(x)) = \left[F_x + F_{y_1}\frac{dy_1}{dx} + \ldots + F_{y_n}\frac{dy_n}{dx}\right]_{x,y(x)}. \tag{5-3}$$

Since the functions $y(x)$, which we have inserted in Eq.(5-3), are supposed to be the solutions of Eq.(5-2), we have

$$\frac{dy_i}{dx} = f_i(x,y(x))$$

$$= \left[f_i(x,y)\right]_{x,y(x)},$$

and

$$\frac{d}{dx} F(x,y(x)) = \left[F_x + f_1(x,y) \frac{\partial F}{\partial y_1} + ... + f_n(x,y) \frac{\partial F}{\partial y_n} \right]_{x,y(x)}$$

$$= \left[DF\right]_{x,y(x)}. \qquad (5\text{-}4)$$

We have defined the linear differential operator

$$D \equiv \frac{\partial}{\partial x} + f_1(x,y) \frac{\partial}{\partial y_1} + ... + f_n \frac{\partial}{\partial y_n}, \qquad (5\text{-}5)$$

as the Lie series operator.

By iteration of Eq.(5-4), we find for the higher derivatives,

$$\frac{d^s}{dx^s} F(x,y(x)) = \left[D^s F\right]_{x,y(x)} \qquad (s = 1, 2, 3, ...). \qquad (5\text{-}6)$$

A series of the following kind:

$$\sum_{s=0}^{\infty} \frac{x^s}{s!} D^s F = F(x,y(x)) + xDF(x,y(x)) + \frac{x^2}{2!} D^2 F(x,y(x)) + ... \qquad (5\text{-}7)$$

satisfies these relationships and is called a Lie series, frequently denoted by the symbol $e^{xD}F$.

5.2 The properties of e^{xD}

(1) The symbol e^{xD} fulfills the following relations:

$$e^{xD}\left[f(x,y) + g(x,y)\right] = \left[e^{xD} f(x,y)\right] + \left[e^{xD} g(x,y)\right]. \qquad (5\text{-}8)$$

and

$$e^{xD}\left[f(x,y)g(x,y)\right] = \left[e^{xD} f(x,y)\right]\left[e^{xD} g(x,y)\right]. \qquad (5\text{-}9)$$

(2) Commutation theorem: If F(y) denotes any function which is analytic in a neighborhood of $(y_1, y_2, \ldots, y_n)$, and $Y_i = \phi_i(x,y) = e^{xD} y_i$, $\left(Y_i\right)_{x=0} = \phi_i(0,y) = y_i$, $i = 1,2,\ldots, n$, then the corresponding power series expansion F(Y) still converges at the point $(Y_1, Y_2, \ldots, Y_n)$. That is

$$F(Y) = \sum_{s=0}^{\infty} \frac{x^s}{s!} D^s F(y),$$

or
$$F(e^{xD} y) = e^{xD} F(y). \tag{5-10}$$

Thus, the function sign F of an analytic function may be commuted with the symbol e^{xD} for the Lie series.

(3) Multiple Lie series:

Let m linear differential operators be given by

$$D_k = f_{k1}(y) \frac{\partial}{\partial y_1} + \ldots + f_{kn}(y) \frac{\partial}{\partial y_n}, \qquad (k = 1, \ldots, m) \tag{5-11}$$

all of which be holomorphic in a certain domain C. We introduce m new independent variables $x_1, x_2, \ldots, x_m$, using them for the multiple Lie series:

$$e^{x_1 D_1 + \ldots + x_m D_m} f(y) = \sum_{s=0}^{\infty} \frac{1}{s!} \left[x_1 D_1 + \ldots + x_m D_m\right]^s f(y). \tag{5-12}$$

Positive constants T_k can be found such that the series (5-12) is absolutely convergent for $(y) \in C$ at $|x| \leq T_k$.

The commutation theorem is valid also for these series:

$$Y_j = e^{x_1 D_1 + \ldots + x_m D_m} y_j, \quad (j = 1, 2, \ldots, n). \tag{5-13}$$

We may change the function sign F of each function analytic in C with the symbol of the Lie series:

$$F(Y) = F(e^{x_1D_1 + \ldots + x_mD_m}y)$$

$$= e^{x_1D_1 + \ldots + x_mD_m} F(y). \tag{5-14}$$

The operators D_k in general cannot be exchanged.

5.3 Lie series perturbation method

(1) The problem and the main theroem.

Consider a system of ordinary differential equations

$$y_i'(x) = f_i(x, y_1(x), \ldots, y_n(x)), \quad (i = 1, \ldots, n) \tag{5-15}$$

with the initial conditions

$$y_i(x_0) = y_{i_0}. \tag{5-16}$$

If the functions f_i satisfy a Lipschitz condition, than the solutions

$$y_1(x), \ldots, y_n(x) \tag{5-17}$$

are unique. But only in a few simple cases can the solutions be written in terms of well-known elementry functions. In most cases, approximation methods must be used.

The method we introduce here is a perturbation method. Hence, there should be given another system of differential equations

$$\hat{y}_i'(x) = \hat{f}_i(x, \hat{y}_1(x), \ldots, \hat{y}_n(x)), \quad (i = 1, \ldots, n) \tag{5-18}$$

whose solutions:

$$\hat{y}_1(x), \ldots, \hat{y}_n(x) \tag{5-19}$$

are known, which satisfy the same initial conditions

$$\hat{y}_i(x_0) = y_{i_0}. \tag{5-20}$$

Next, we define the differential operators

$$D \equiv \frac{\partial}{\partial x} + \sum_{k=1}^{n} f_k(x, y_1, \ldots, y_n)\frac{\partial}{\partial y_k} \tag{5-20}$$

belonging to the given system (5-15), and

$$D_1 \equiv \frac{\partial}{\partial x} + \sum_{k=1}^{n} \hat{f}_k(x,\hat{y}_1,\ldots,\hat{y}_n)\,\frac{\partial}{\partial y_k} \tag{5-22}$$

belong to the chosen system (5-18). Then

$$D_2 = \sum_{k=1}^{n}\Big[f_k(x,y_1,\ldots,y_n) - \hat{f}_k(x,\hat{y}_1,\ldots,\hat{y}_n)\Big]\frac{\partial}{\partial y_k}$$

$$= D - D_1 \tag{5-23}$$

taking into account the discrepancy between the original and the chosen system.

Now, let $f_k(x,y_1,\ldots,y_n)$ and $\hat{f}_k(x,\hat{y}_1,\ldots,\hat{y}_n)$ $(k = 1,\ldots,n)$

be continuous in the compact domain

$$C = \{(x,y_1,\ldots,y_n)\ x\in[x_0,\ x_0+a]\ ,\ |y_i - y_{i_0}|\leqslant b\ (i=1,\ldots,n)\} \tag{5-24}$$

of the $(x,y_1,\ldots,y_n)$-space. Then they are bounded in C. The conditions

$$|f_k(x,y_1,\ldots,y_n)\leqslant A_0,\quad |\hat{f}_k(x,\hat{y}_1,\ldots,\hat{y}_n)|\leqslant B_0, \tag{5-25}$$

and the Peano-theorem [111] guarantee the existence of corresponding solutions $y_k(x)$ of (5-15), and $\hat{y}_k(x)$ of (5-18) at least for

$$x\in[x_0,x_0+h],$$

where

$$h = \min\left(a,\ \frac{b}{A_0},\ \frac{b}{B_0}\right). \tag{5-26}$$

The main theorem

If $f_1(x,y_1,\ldots,y_n),\ldots,f_n(x,y_1,\ldots,y_n)$ and $\hat{f}_1(x,\hat{y}_1,\ldots,\hat{y}_n),\ldots,$ $\hat{f}_n(x,\hat{y}_1,\ldots,\hat{y}_n)$ are s-times continuously differentiable $(s\geqslant 0)$ in C then the following formula holds, at least for $x\in[x_0,x_0+h]$:

$$y_k(x) = \hat{y}_k(x) + \sum_{\alpha=0}^{s} \int_{x_0}^{x} \frac{(x-\xi)^\alpha}{\alpha!} \left[D_2 D^\alpha y_k\right]_{\xi,\hat{y}(\xi)} d\xi + R_{ks}(x)$$

$$= \bar{y}_k(x) + R_{ks}(x) \qquad (k = 1,\ldots, n) \qquad (5\text{-}27)$$

where

$$R_{ks}(x) = \int_{x_0}^{x} \frac{(x-\xi)^s}{s!} \left\{\left[D^{s+1} y_k\right]_{\xi,y(\xi)} - \left[D^{s+1} y_k\right]_{\xi,\hat{y}(\xi)}\right\} d\xi \qquad (5\text{-}28)$$

and

$$\bar{y}_k(x) = \hat{y}_k(x) + \sum_{\alpha=0}^{s} \int_{x_0}^{x} \frac{(x-\xi)^\alpha}{\alpha!} \left[D_2 D^\alpha y_k\right]_{\xi,\hat{y}(\xi)} d\xi . \qquad (5\text{-}29)$$

Proof:

First, we introduce three auxiliary formulas. We recognize that:

(a) If $g(\xi)$ and $h(\xi)$ are continuously differentiable functions with $g(\xi_0) = h(\xi_0)$, then

$$g(\xi) - h(\xi) = \int_{\xi_0}^{\xi} \Big(g'(\eta) - h'(\eta)\Big) d\eta. \qquad (5\text{-}30)$$

(b) Let $y_1(x),\ldots,y_n(x)$ be the solutions of the original problem and $\hat{y}_1(x),\ldots,\hat{y}_n(x)$ be the solutions of the chosen equations. If now $F(x,y_1,\ldots,y_n)$ is sufficiently differentiable, then for the derivative of $F(x,y)$ and $F(x,\hat{y})$, we have, by the chain rule:

$$\frac{d}{dx} F(x,y) = \left[\frac{\partial F(x,y)}{\partial x} + \frac{\partial F(x,y)}{\partial y_1} f_1(x,y) + \ldots + \frac{\partial F(x,y)}{\partial y_n} f_n(x,y)\right]_{x,y(x)}$$

$$= \left[DF(x,y)\right]_{x,y(x)}, \qquad (5\text{-}31)$$

and

$$\frac{d}{dx} F(x,\hat{y}) = \left[\frac{\partial F(x,\hat{y})}{\partial x} + \frac{\partial F(x,\hat{y})}{\partial y_1} f_1(x,\hat{y}) + \ldots + \frac{\partial F(x,\hat{y})}{\partial y_n} f_n(x,\hat{y})\right]_{x,\hat{y}(x)}$$

$$= \left[DF(x,\hat{y})\right]_{x,\hat{y}(x)}, \qquad (5\text{-}31)$$

respectively. Finally,

$$(c)\int_{x_0}^{x} \frac{(x-\xi)^{\alpha}}{\alpha!}\int_{x_0}^{\xi} k(\eta)d\eta d\xi = \int_{x_0}^{x}\frac{(x-\xi)^{\alpha+1}}{(\alpha+1)!}\,k(\xi)d\xi. \qquad (5\text{-}33)$$

This can be proven easily by integration by parts.

The left hand side of (5-33) gives:

$$\left[-\frac{(x-\xi)^{\alpha+1}}{(\alpha+1)!}\int_{x_0}^{\xi} k(\eta)d\eta\right]\Bigg|_{\xi=x_0}^{\xi=x} + \int_{x_0}^{x}\frac{(x-\xi)^{\alpha+1}}{(\alpha+1)!}\,k(\xi)d\xi$$

where the first term vanishes by inserting the integral bounds.

Now, we may begin the proof of the main theorem. We write

$$y_k(x) = \hat{y}_k(x) + \left[y_k(x) - \hat{y}_k(x)\right] \qquad (k = 1,\ldots, n)$$

by (a) and (b) we have

$$\begin{aligned} y_k(x) - \hat{y}_k(x) &= \int_{x_0}^{x}\left[y_k'(\eta) - \hat{y}_k'(\eta)\right]d\eta \\ &= \int_{x_0}^{x}\{\left[Dy_k\right]_{\eta,y(\eta)} - \left[D_1 y_k\right]_{\eta,\hat{y}(\eta)}\}d\eta \\ &= \int_{x_0}^{x}\{\left[Dy_k\right]_{\eta,\hat{y}(\eta)} - \left[D_1 y_k\right]_{\eta,\hat{y}(\eta)} + \left[Dy_k\right]_{\eta,y(\eta)} \\ &\qquad - \left[Dy_k\right]_{\eta,\hat{y}(\eta)}\}d\eta \\ &= \int_{x_0}^{x}\left[D_2 y_k\right]_{\eta,\hat{y}(\eta)}d\eta + R_{k_0}(x), \end{aligned} \qquad (5\text{-}34)$$

where

$$R_{k0}(x) = \int_{x_0}^{x}\{\left[Dy_k\right]_{\eta,y(\eta)} - \left[Dy_k\right]_{\eta,\hat{y}(\eta)}\}d\eta.$$

This proves our main theorem for $s = 0$.

Now, for any positive integer s, and $\alpha<s$, then by (a), (b), and (c):

$$\begin{aligned} R_{k\alpha}(x) &= \int_{x_0}^{x}\frac{(x-\xi)^{\alpha}}{\alpha!}\{\left[D^{\alpha+1}y_k\right]_{\xi,y(\xi)} - \left[D^{\alpha+1}y_k\right]_{\xi,\hat{y}(\xi)}\}d\xi \\ &= \int_{x_0}^{x}\frac{(x-\xi)^{\alpha}}{\alpha!}\int_{x_0}^{\xi}\{(\left[D^{\alpha+1}y_k\right]_{\eta,y(\eta)})' - (\left[D^{\alpha+1}y_k\right]_{\eta,\hat{y}(\eta)})'\}d\eta d\xi \end{aligned}$$

$$= \int_{x^0}^{x} \frac{(x-\xi)^{\alpha}}{\alpha!} \int_{x_0}^{\xi} \{ \left[DD^{\alpha+1} y_k \right]_{\eta, y(\eta)} - \left[D_1 D^{\alpha+1} y_k \right]_{\eta, \hat{y}(\eta)} \} d\eta d\xi$$

$$= \int_{x_0}^{x} \frac{(x-\xi)^{\alpha+1}}{(\alpha+1)!} \{ \left[DD^{\alpha+1} y_k \right]_{\xi, \hat{y}(\xi)} - \left[D_1 D^{\alpha+1} y_k \right]_{\xi, \hat{y}(\xi)}$$

$$+ \left[DD^{\alpha+1} y_k \right]_{\xi, y(\xi)} - \left[DD^{\alpha+1} y_k \right]_{\xi, \hat{y}(\xi)} \} d\xi$$

$$= \int_{x_0}^{x} \frac{(x-\xi)^{\alpha+1}}{(\alpha+1)!} \left[D_2 D^{\alpha+1} y_k \right]_{\xi, \hat{y}(\xi)} d\xi + R_{k, \alpha+1}(x), \qquad (5\text{-}35)$$

where

$$R_{k,\ \alpha+1}(x) = \int_{x_0}^{x} \frac{(x-\xi)^{\alpha+1}}{(\alpha+1)!} \{ \left[D^{\alpha+2} y_k \right]_{\xi, y(\xi)} - \left[D^{\alpha+2} y_k \right]_{\xi, \hat{y}(\xi)} \} d\xi. \qquad (5\text{-}36)$$

Thus, the main theorem is valid if $\alpha<s$. From Eq.(5-29), we notice that our method is an expansion of the solutions in the neighborhood of chosen functions, whereas the Taylor series is an expansion in the neighborhood of a point.

(2) Order of the remainder term.

If, in addition to the assumptions in the main theorem,

$$| D^s f_i(x, y_1, \ldots, y_n)_{x, y^*} - D^s f_i(x, y_1, \ldots, y_n)_{x, y^{**}} |$$

$$\leq K_s \sum_{k=1}^{n} | y_k^* - y_k^{**} | \qquad (5\text{-}37)$$

for $(x, y_1^*, \ldots, y_n^*) \in C$ and $(x, y_1^{**}, \ldots y_n^{**}) \in C$ (that is the Lipschitz condition for the functions $D^s f_1, \ldots, D^s f_n$ with a constant K_s in C),

and $$|y_i(x) - \vartheta_i(x)| \leq M \frac{|x_0 - x|^{m+1}}{(m+1)!} \quad \text{for } x \in [x_0, x_0 + h], \qquad (5\text{-}38)$$

where M is a constant and m is an integer, then

$$|R_{is}(x)| \leq M \frac{K_s n |x - x_0|^{m+s+2}}{(m+s+2)!} \quad \text{for} \quad x \in [x_0, x_0 + h]. \tag{5-39}$$

Proof: Since $D^{s+1}y_i = D^s(Dy_i) = D^s f_i$, and because of (5-37) and (5-38), we can estimate R_{is}

$$|R_{is}(x)| = \left| \int_{x_0}^{x} \frac{(x-\xi)^s}{s!} \left\{ \left[D^{s+1} y_i \right]_{\xi, y(\xi)} - \left[D^{s+1} y_i \right]_{\xi, \hat{y}(\xi)} \right\} d\xi \right|$$

$$\leq \left| \int_{x_0}^{x} \frac{|x-\xi|^s}{s!} K_s \sum_{k=1}^{n} |y_k(\xi) - \hat{y}_k(\xi)| d\xi \right|$$

$$\leq \left| \int_{x_0}^{x} \frac{|x-\xi|^s}{s!} K_s n M \frac{|\xi - x_0|^{m+1}}{(m+1)!} d\xi \right|.$$

Introducing

$$\int_{x_0}^{x} \frac{(x-\xi)^\alpha}{\alpha!} \frac{(\xi - x_0)^\beta}{\beta!} d\xi = \frac{(x-x_0)^{\alpha+\beta+1}}{(\alpha+\beta+1)!}, \tag{5-40}$$

where α and β are positive integers, we get (5-39).

(3) Iterative method interpretation

It is indicated in section V - 3 that the solutions to the perturbed system must be known. In our case, for example, we use the first m terms of a Taylor series. We get the first approximate solutions from Eq. (5-27) by substituting the perturbed solutions for $\hat{y}_k$ and neglecting the remainders. In this way, we have an iteration process which yields the desired solutions. To put it another way, let us introduce a left subscript ν ($\nu = 0, 1, \ldots$) to denote the index of steps of the iteration. Then,

$${}_0 y_i(x) = \hat{y}_i(x), \qquad (i = 1, \ldots, n) \tag{5-41}$$

and by Eq.(5-27), we have

$$ {}_1y_i(x) = \hat{y}_i(x) + \sum_{\alpha=0}^{s} \int_{x_0}^{x} \frac{(x-\xi)^\alpha}{\alpha!} \left[{}_0D_2 D^\alpha y_i \right]_{\xi, y(\xi)} d\xi . $$

In general, we calculate ${}_{\nu+1}y_i(x)$ by

$$ {}_{\nu+1}y_i(x) = {}_\nu y_i(x) + \sum_{\alpha=0}^{s} \int_{x_0}^{x} \frac{(x-\xi)^\alpha}{\alpha!} \left[{}_\nu D_2 D^\alpha y_i \right]_{\xi, {}_\nu y(\xi)} d\xi \qquad (5\text{-}42) $$

where

$$ {}_\nu D_2 \equiv \sum_{k=1}^{n} \{ f_k(x, y_1, \ldots, y_n) - {}_\nu f_k(x) \} \frac{\partial}{\partial y_k} . \qquad (5\text{-}43) $$

(4) Convergence proof

If the functions $D^s f_1(x, y_1, \ldots, y_n), \ldots, D^s f_n(x, y_1, \ldots, y_n)$ are continuous and satisfy a Lipschitz condition (5-37) in C, given by Eq.(5-24), then

$$ \lim_{\nu \to \infty} {}_\nu y_i(x) = y_i(x). $$

Proof:

Recall that,

(a) Under these assumptions the existence and uniqueness of the solution are guaranteed, at least for $x \in [x_0, x_0 + h]$;

(b) If the functions ${}_\nu y_i(x)$ are (s+1)-times differentiable and $(x, {}_\nu y_i(x)) \in C$ for $x \in [x_0, x_0 + h_\nu]$, then ${}_{\nu+1}y_i(x)$ are also (s+1)-times differentiable for $x \in [x_0, x_0 + h_\nu]$. The functions ${}_\nu f_i(x)$ are, therefore, s-times differentiable.

Note that

$$\frac{d^{\alpha}}{dx^{\alpha}} \int_{x_0}^{x} \frac{(x-\xi)^{\alpha-1}}{(\alpha-1)!} \left[{}_{\nu}D_2 D^{\alpha} y_i\right]_{\xi,\,{}_{\nu}y(\xi)} d\xi = \left[{}_{\nu}D_2 D^{\alpha} y_i\right]_{x,\,{}_{\nu}y(x)}$$

is still $(s-\alpha)$-times differentiable; therefore each term of

$${}_{\nu+1}f_i(x) = f_i(x, {}_{\nu}y_1(x), \ldots, {}_{\nu}y_n(x)) + \sum_{\alpha=1}^{s} \int_{x_0}^{x} \frac{(x-\xi)^{\alpha-1}}{(\alpha-1)!} \left[{}_{\nu}D_2 D^{\alpha} y_i\right]_{\xi,\,{}_{\nu}y(\xi)} d\xi,$$

and the sum itself are s-times differentiable. This together with

$${}_{\nu}y_i(x) = y_{i_0} + \int_{x_0}^{x} {}_{\nu}f_i(\xi)\,d\xi$$

proves the assertion.

Thus the iterated functions ${}_{\nu+1}y_1(x), \ldots, {}_{\nu+1}y_n(x)$ remain (s+1)-times differentiable in $\bigcap_{\mu=0}^{\nu} [x_0, x_0+h_{\mu}]$ if the starting functions ${}_{0}y_i(x)$ have this property. Hence they may be inserted into (5-42).

Now, we first have to show that there exists an interval $[x_0, x_0+h]$ with $h \neq 0$ such that $(x, {}_{\nu}y_i(x)) \in C$ for $x \in [x_0, x_0+h]$. (Or in other words, we have to show that there is an $h \neq 0$ such that $[x_0, x_0+h] \subset \bigcap_{\mu=0}^{\infty} [x_0, x_0+h_{\mu}]$.)

For this we do the following:

Functions which are continuous in the compact domain C are uniformly continuous. The assumptions stated lead to numbers A_0, and $C_0, \ldots, C_s$ such that

$$\left.\begin{aligned} &\left|f_i(x, y_1, \ldots, y_n)\right| \leq A_0 && (i = 1, \ldots, n) \\ &\left|\left[\frac{\partial}{\partial y_k} D^{\alpha} y_i\right]_{x,y}\right| \leq C_{\alpha} && \begin{matrix}(k = 1, \ldots, n) \\ (\alpha = 0, \ldots, s)\end{matrix} \end{aligned}\right\} \qquad (5\text{-}44)$$

for $(x, y_1, \ldots, y_n) \in C$.

Now let

$$|{}_0f_i(x)| \leq B_0 \text{ for } x \in [x_0, x_0+h]. \tag{5-45}$$

Restricting the interval to $[x_0, x_0+\bar{h}]$, with

$$\bar{h} = \min\left[a, \frac{b}{B_0}\right] \qquad \text{(first restriction)}, \tag{5-46}$$

we have the estimate that

$$\left|{}_0y_k(x) - y_{k_0}\right| = \left|\int_{x_0}^{x} {}_0f_k(\xi)d\xi\right| \leq B_0\left|x - x_0\right| \leq b. \tag{5-47}$$

Thus we obtain the rough bounds

$$|\,{}_0D_2D^{\alpha}y_i\,|_{x,y} \leq (A_0 + B_0)nC_{\alpha} = A_{\alpha} \tag{5-48}$$

and $$|{}_1f_i(x)| \leq |f_i(x, {}_0y_1(x), \ldots, {}_0y_n(x))|$$

$$+\left|\sum_{\alpha=1}^{s}\int_{x_0}^{x} \frac{(x-\xi)^{\alpha-1}}{(\alpha-1)!}[{}_0D_2D^{\alpha}y_i]_{\xi,\,{}_0y(\xi)}d\xi\right|$$

$$\leq \sum_{\alpha=0}^{s} \frac{|x - x_0|^{\alpha}}{\alpha!} A_{\alpha} = B_1. \tag{5-49}$$

Under the assumption $A_0<B_0$, we restrict the x-interval to $[x_0, x_0+h]$, with

$$h = \min\left[a, \frac{b}{B_0}, \bar{a}\right] \qquad \text{(second restriction)},$$

where $\bar{a}$ is the positive root of the polynomial

$$p(t) = B_0 - \sum_{\alpha=0}^{s} \frac{t^{\alpha}}{\alpha!}A_{\alpha}.$$

Then $B_1 \leq B_0$, from which follows

$$|{}_{\nu+1}f_i(x)| \leq |f_i(x, {}_{\nu}y_1(x), \ldots, {}_{\nu}y_n(x))|$$

$$+\left|\sum_{\alpha=1}^{s}\int_{x_0}^{x} \frac{(x-\xi)^{\alpha-1}}{(\alpha-1)!}[{}_{\nu}D_2D^{\alpha}y_i]_{\xi,\,{}_{\nu}y(\xi)}d\xi\right|$$

$$\leqslant \sum_{\alpha=0}^{s} \frac{|x - x_0|^{\alpha}}{\alpha!} A_{\alpha} \leqslant B_0,$$

and

$$|{}_{\nu+1} y_k(x) - y_{k_0}| = \left|\int_{x_0}^{x} {}_{\nu+1}f_k(\xi)d\xi\right| \leqslant b, \tag{5-50}$$

for all $\nu = 0,1,\ldots$. Since, for the estimation of ${}_{\nu+1}f_i(x)$, we have only to repeat the above techniques beginning with (5-45) by considering ${}_{\nu}f_k$, ${}_{\nu}y_k$, and ${}_{\nu}D_2$ instead of ${}_{0}f_k$, ${}_{0}y_k$, and ${}_{0}D_2$ $(k = 1,\ldots,n)$, no further restrictions on the x-interval are necessary to ensure that $|{}_{\nu+1}f_i(x)| \leqslant B_0$.

Now, we show that the sequences of functions ${}_{\nu}y_i(x)$ converge toward $y_i(x)$. This is easily done, because in $[x_0, x_0+h]$ the main theorem holds. Written with ${}_{\nu}y_1(x),\ldots,{}_{\nu}y_n(x)$ as approximate solutions, we have:

$$y_i(x) = {}_{\nu}y_i(x) + \sum_{\alpha=0}^{s} \int_{x_0}^{x} \frac{(x-\xi)^{\alpha}}{\alpha!} [{}_{\nu}D_2 D^{\alpha} y_i]_{\xi, {}_{\nu}y(\xi)} d\xi + {}_{\nu}R_{is}(x)$$

$$= {}_{\nu+1}y_i(x) + {}_{\nu}R_{is}(x). \tag{5-51}$$

If in the interval $[x_0, x_0+h]$

$$|y_i(x) - {}_{0}y_i(x)| \leqslant 2\bar{b}, \qquad (\bar{b} < b)$$

then we have (using the Lipschitz condition (5-37))

$$|y_i(x) - {}_{1}y_i(x)| = |{}_{0}R_{is}(x)| \leqslant 2\bar{b} \frac{K_s n |x - x_0|^{s+1}}{(s+1)!}.$$

Induction over ν then leads to the following result:

If $\quad |y_i(x) - {}_{0}y_i(x)| \leqslant 2\bar{b}$ for $x \in [x_0, x_0+h]$ $(\bar{b} \leqslant b)$

where $\quad b = \underset{i}{\mathrm{Max}} |y_i - y_{i_0}|,$

then

$$|y_i(x) - {}_\nu y_i(x)| < 2\bar{b}\frac{\left(K_s n|x - x_0|^{s+1}\right)^\nu}{[(s+1)\nu]!} \qquad \begin{matrix}(i = 1,2,\ldots,n)\\ (\nu = 0,1,\ldots..)\end{matrix} \tag{5-52}$$

To prove this we use (5-51) for the corresponding index ν, and the Lipschitz condition (5-37), and integrate with the help of (5-40)

According to (5-38) the errors decrease with increasing ν.

Hence, $$\lim_{\nu \to \infty} {}_\nu y_i(x) = y_i(x)$$

for $x \in [x_0, x_0+h]$. This completes the proof of the convergence. Incidentally, if

$$|y_i(x) - {}_0 y_i(x)| \leq M\frac{|x-x_0|^{m+1}}{(m+1)!}$$

then (5-52) becomes

$$|y_i(x) - {}_0 y_i(x)| \leq M|x - x_0|^{m+1}\frac{[K_s n|x-x_0|^{s+1}]^\nu}{[m+1+\nu(s+1)]!}. \tag{5-52'}$$

Next, we try to find the error bounds without knowledge about the solution. We have

$${}_{\nu+1}y_i(x) - {}_\nu y_i(x) = y_i(x) - {}_\nu y_i(x) + {}_{\nu+1}y(x) - y_i(x)$$

$$= {}_{\nu-1}R_{is}(x) - {}_\nu R_{is}(x) \tag{5-53}$$

$$= \int_{x_0}^{x}\frac{(x-\xi)^s}{s!}\{[D^{s+1}y_i]_{\xi,\nu}y(\xi) - [D^{s+1}y_i]_{\xi,\nu-1}y(\xi)\}d\xi.$$

If for the first iterated functions ${}_1y_1(x),\ldots,{}_1y_n(x)$,

then by induction and applying the Lipschitz condition (5-37),(5-38) and (5-40), we have

$$|{}_{\nu+1}y_i(x) - y_i(x)| \leq 2b'\frac{(K_s n|x - x_0|^{s+1})^\nu}{[(s+1)\nu]!}, \tag{5-55}$$

where $x \in [x_0, x_0+h]$, $(i = 1,\ldots, n)$, $(\nu = 0,1,\ldots..)$.

Specifically, if

$$|{}_1y_i(x) - {}_0y_i(x)| \leq M\frac{|x-x_0|^{m+1}}{(m+1)!}$$

then Eq.(5-55) becomes

$$|{}_{\nu+1}y_i(x) - {}_\nu y_i(x)| \leq M|x-x_0|^{m+1}\frac{[K_s n|x-x_0|^{s+1}]^\nu}{[m+1+\nu(s+1)]!} \qquad (5\text{-}55')$$

From

$${}_\mu y_i(x) - {}_\nu y_i(x) = \sum_{\rho=\nu}^{\mu-1}\{{}_{\rho+1}y_i(x) - {}_\rho y_i(x)\}, \qquad (\mu>\nu)$$

we can write

$$y_i(x) - {}_\nu y_i(x) = \sum_{\rho=\nu}^{\infty}\{{}_{\rho+1}y_i(x) - {}_\rho y_i(x)\}, \qquad (5\text{-}56)$$

and by (5-55') we have

$$|y_i(x) - {}_\nu y_i(x)| \leq M|x-x_0|^{m+1}\sum_{\rho=\nu}^{\infty}\frac{(K_s n|x-x_0|^{s+1})^\rho}{(m+1)![(s+1)\rho]!}. \qquad (5\text{-}57)$$

Similarly, we can iterate the main formula Eq.(5-27). Recall that, ${}_0y_i(x) = \hat{y}_i(x)$, and ${}_1y_i(x) = \bar{y}_i(x)$. Thus, from (5-27) we have

$$\begin{aligned} y_i(x) - \bar{y}_i(x) &= R_{is}(x) \\ &= \int_{x_0}^{x}\frac{(x-\xi)^s}{s!}\{[D^{s+1}y_i]_{\xi,y(\xi)} - [D^{s+1}y_i]_{\xi,\hat{y}(\xi)}\}d\xi \\ &= \int_{x_0}^{x}\frac{(x-\xi)^s}{s!}\{[D^{s+1}y_i]_{\xi,\bar{y}(\xi)} - [D^{s+1}y_i]_{\xi,\hat{y}(\xi)}\}d\xi \qquad (5\text{-}58) \\ &\quad + \int_{x_0}^{x}\frac{(x-\xi)^s}{s!}\{[D^{s+1}y_i]_{\xi,y(\xi)} - [D^{s+1}y_i]_{\xi,\bar{y}(\xi)}\}d\xi \\ &= R^*_{is}(x) + R^{**}_{is}(x). \end{aligned}$$

We see that $R^{**}_{is}(x)$ is of higher order than $R^*_{is}(x)$, Hence, in actual computation we can use $R^*_{is}(x)$ instead of $R_{is}(x)$.

5.4 Numerical Consideration

Recurrence Relationships

Recurrence Relationships of Simple Derivatives. In a system of differential equations, like

$$\frac{dy_i}{dx} = f_i(x,y_1,\ldots, y_n), \quad (i = 1,\ldots, n),$$

one can display each f_i as the result of the final operation in a finite sequence of arithmetic operations, each of which defines a partial result

$$R_s(x,y_1,\ldots,y_n) = P_s(x,y_1,\ldots,y_n)*Q_s(x,y_1,\ldots,y_n),$$

where * represents one of the arithmetic operations +, -, ·, /, etc.

and $s = 1, 2, \ldots, S_i$ is a finite sequence.

We want to apply the appropriate rule for the jth derivative of a sum, difference, product, or quotient etc., corresponding to each partial result $R_s(x,y_1,\ldots,y_n)$ so that we obtain a sequence of subroutines for each $d^jR_s(x,y_1,\ldots,y_n)/dx^j$, and hence for each $f_i^{(j)}$, since $d^{j+1}y_i/dx^{j+1} = f_i^{(j)}$.

Let us abbreviate $\frac{1}{j!}\frac{d^jR}{dx^j}$ of a function $R(x,y_1,\ldots,y_n)$ as $(R)_j$. Then for two functions $P(x,y_1,\ldots,y_n)$, and $Q(x,y_1,\ldots,y_n)$ we have

$$(P\pm Q)_j = (P)_j \pm (Q)_j, \quad (j = 1,2,\ldots, J)$$

$$(PQ)_j = \sum_{r=0}^{j} (P)_r(Q)_{j-r},$$

and $$\left(\frac{P}{Q}\right)_j = \frac{1}{Q}\left[(P)_j - \sum_{r=0}^{j} (P)_r(Q)_{j-r}\right].$$

The second relationship follows directly from the expression

$$\frac{d^j}{dx^j}(PQ) = \sum_{r=0}^{j}\binom{j}{r} P^{(r)}Q^{(j-r)}.$$

Thus, $$\frac{1}{j!}\frac{d^j}{dx^j}(PQ) = \sum_{r=0}^{j}\frac{1}{r!}P^{(r)}\frac{1}{(j-r)!}Q^{(j-r)}$$

$$= \sum_{r=0}^{j}(P)_r(Q)_{j-r},$$

and so $$(PQ)_j = \sum_{r=0}^{j}(P)_r(Q)_{j-r}.$$

The third relationship is the consequence of direct application of the second relationship.

Each of the quantities P and Q in the above expressions can be: (1) a constant, (2) one of the variables y_i, or (3) one of the intermdiate results R.

These relationships can be found in the literature of the mid-50's[112]. More relationships were established in the 60's, mostly due to Gibbons[113] or Moore[114], and Leawitt[115].

Since for any function F, we have $((F)_1)_j = (j+1)(F)_{j+1}$, then for a system of differential equations

$$\frac{dy_i}{dx} = f_i(x,y_1,\ldots,y_n),$$

we add $$(y_i)_{j+1} = \frac{1}{j+1}(f_i)_j$$

with which the procedure can be repeated, leading to a recurrent calculation of the expression $(y_i)_{j+1}$.

Recurrence Relationships for Expressions with Two Differential Operators. As was shown in Eq.(5-27), combining the perturbation method with the Lie series method gives rise to a D_2D^{α} term in the expression. This requires additional recurrence relationships to carry out the calculation of the differentiation involving the operations D_2D^{α}.

Let the second differential operator be represented by $\bar{D}$. Operating with $\bar{D}$ on

$$(R)_j = \frac{1}{j!} D^j R(x,y_1,\ldots,y_n),$$

we get

$$\bar{R}_j = \bar{D}(R)_j.$$

Applying the operator $\bar{D}$ to the formulas obtained for D^j, and using the notation we just introduced, we have:

for a sum or difference $r = p \pm q$,

$$\bar{R}_j = \bar{P}_j \pm \bar{Q}_j;$$

for a product $r = p \cdot q$,

$$R_j = \sum_{r=0}^{j} \left[P_r (Q)_{j-r} + (P)_r \bar{Q}_{j-r} \right];$$

and for a quotient $r = p/q$,

$$\bar{R}_j = \{ \bar{P}_j - \sum_{r=0}^{j-1} \left[\bar{P}_r (Q)_{j-r} + (P)_r \bar{Q}_{j-r} \right] - (P)_j Q_0 \} / (Q)_0.$$

In deriving this expression, we first multiplied the simple recurrence relationship by $(Q)_0$, then operated $\bar{D}$ on it.

Finally,

$$\bar{y}_{i,\mu+1} = \frac{1}{\mu+1} \bar{f}_{i,\mu}.$$

The operator $\bar{D}$ here can be either (1) D_2, or (2) $\frac{\partial}{\partial y_k}$, which appears in a simple Lie series expansion. In the first case, we have the expression

$$\bar{y}_{i,\alpha} = \frac{D_2 D^{\alpha} y_i}{\alpha!},$$

and it has to be started with the initial values

$$\bar{y}_{i,0} = D_2 y_i = f_i(x,y_1,\ldots,y_n) - \hat{f}_i(x,y_1,\ldots,y_n).$$

In the second case we have

$$\bar{y}_{i,\alpha} = \frac{1}{\alpha!} \frac{\partial}{\partial y_k} D^{\alpha} y_i.$$

Here, it starts with

$$\bar{y}_{i,0} = \begin{cases} 1, & \text{for } i = k, \\ 0, & \text{for } i \neq k. \end{cases}$$

In both events, if we encounter the independent variable x, or a constant, the results vanish. That is,

$$\bar{X}_0 = \bar{X}_1 = \ldots = 0,$$

and $$\bar{C}_0 = \bar{C}_1 = \ldots = 0.$$

(2) The concept of transfer matrix.

Let $y_i(x)$ be solutions of the given differential equations for the initial values y_{k_0}. The matrix

$$H(x) = \left[H_{ik}(x)\right] = \left[\frac{\partial y_i(x)}{\partial y_{k_0}}\right] \tag{5-62}$$

which consists of the derivatives of the solutions $y_i(x)$ with respect to the kth initial value y_{k_0}, is then called the transfer matrix pertaining

to $y(x)$.

In other words, the transfer matrix describes, in first approximation, the variation of the solutions y_i at the point x if the initial values y_{k_0} are changed. When we change the initial values y_{i_0}, by ε_{i_0}, the solutions y_i at the point x will in the first approximation change by

$$\varepsilon_i(x) = \frac{\partial y_i(x)}{\partial y_{1_0}} \varepsilon_{1_0} + \ldots + \frac{\partial y_i(x)}{\partial y_{n_0}} \varepsilon_{n_0}.$$

Thus,

$$\begin{bmatrix} \varepsilon_1(x) \\ \cdot \\ \cdot \\ \varepsilon_n(x) \end{bmatrix} = \begin{bmatrix} \frac{\partial y_i(x)}{\partial y_{1_0}} & \cdots\cdots & \frac{\partial y_1(x)}{\partial y_{n_0}} \\ \cdot & \cdots\cdots & \cdot \\ \frac{y_n(x)}{\partial y_{1_0}} & \cdots\cdots & \frac{y_n(x)}{\partial y_{n_0}} \end{bmatrix} \begin{bmatrix} \varepsilon_{1_0} \\ \cdot \\ \cdot \\ \varepsilon_{n_0} \end{bmatrix}$$

or, in vector form,

$$\varepsilon(x) = H(x)\varepsilon_0. \tag{5-63}$$

From (5-63) we see that errors committed in the numerical integration can be mapped to any fixed point by means of the transfer matrices. These also describe how an error committed at a certain place influences the final result.

(3) Step size control.

There are three possible schemes for step size control. These are: (a) constant step size, (b) step size control using the local truncation errors, and (c) optimal step size control.

The idea of step size control using the local truncation errors is to choose a step size which keeps the local truncation errors below the

preset bounds. Let $R_{is}(x_0+h)$ be the remainders of the solution $y_i(x_0+h)$, and γ_i the desired sizes of the local truncation errors. Then we define the error ratio as

$$\eta = \max_i \frac{|R_{is}(x_0+h)|}{\gamma_i} .$$

For a control of the step size h, one tries to keep $\eta \simeq 1$.

From Eq.(5-39), it shows that $R_{is}(x_0+h)$ is on the order of m+s+2; it follows that η is proportional to h^{m+s+2}. That is, if we calculate one step with step size h, then

$$\eta \propto h^{m+s+2}.$$

Suppose $\bar{h}$ is the second step size, and $\bar{\eta}$ the error ratio for the second step, and $\bar{\eta} \propto \bar{h}^{m+s+2}$,

then $$\frac{\eta}{\bar{\eta}} = \left(\frac{h}{\bar{h}}\right)^{m+s+2}.$$

Since we want to keep $\bar{\eta} \simeq 1$, then

$$\bar{h} = h \sqrt[m+s+2]{\frac{1}{\eta}},$$

and we see that we have the equation of a parabola. One can plot $\bar{h}$ against η as shown in the following figure.

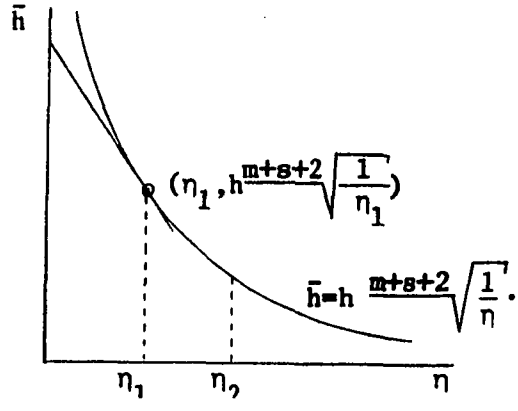


Fig. 3. Step Size Control Using the Local Truncation Error.

If $\eta > 1$, it is evident from the definition of η that the remainder is greater than the desired size of the local truncation error we set. In this case the step size, $\bar{h}$, is recalculated. Otherwise, the original $\bar{h}$ is taken as the step size for the calculation of the solution.

If $\eta << 1$, as is indicated by the sketch, a too-rapid increases of the step size occurs and causes oscillation in the solution. Thus, from a practical point of view, we choose upper and lower limits of η, for example, $\eta_1 = 0.1$ or 0.01, and $\eta_2 = 1.1$ or 1.2.

For $\eta_1 < \eta < \eta_2$ we use the formula

$$\bar{h} = h \sqrt[m+s+2]{\frac{1}{\eta}}$$

to calculate the step size; and for $\eta < \eta_1$, we replace the parabola by its tangent at $\eta = \eta_1$, that is,

$$\bar{h} = h\frac{m+s+3}{m+s+2} \sqrt[m+s+2]{\frac{1}{\eta_1}} \{1 - \frac{\eta}{(m+s+3)\eta_1}\}.$$

Optimal step size control: From the concept of the transfer matrix if e_j is an error committed at the point x_j, then its propagation at x_N is given by

$$e^{(N)} = H(x_N)H^{-1}(x_j)e_j.$$

We want to know how the step sizes $h_1, h_2, \ldots, h_N$ are to be chosen to give minimal final error.

Neglecting rounding errors, we may write that

$$e_j = \psi_j h_j^{p+1}$$

where p is the order of the method, that is m+s+1. Then, we have the relationship that

$$e^{(N)} = H(x_N)H^{-1}(x_j)\psi_j h_j^{p+1} = \chi_j h_j^{p+1}.$$

We try to minimize

$$\sum_{j=1}^{N} e_j^{(N)} = \sum_{j=1}^{N} \chi_j h_j^{p+1}$$

under the condition that

$$\sum_{j=1}^{N} h_j = x_N - x_0$$

$$= \text{constant.}$$

The method of Lagrange-multipliers yields the result

$$h_j = \frac{C_1}{p\sqrt{\chi_j}}.$$

Thus, for local error we can write

$$e_j = \psi_j h_j^{p+1}$$

$$= \frac{\psi_j C_2}{\chi_j \, p\sqrt{\chi_j}}$$

$$= \frac{C_3 h_j}{H(x_N)H^{-1}(x_j)},$$

that is, the h_j are optimal if

$$\frac{H(x_N)H^{-1}(x_j)e_j}{h_j} \simeq C_3.$$

In other words, if the contribution of each step to the final result is proportional to its step size, the total truncation error will be the minimum. In the above expression, $H(x_N)$ is a constant and need not be known at the moment, but it can be calculated when the solution at x_N

is obtained, since $H(x_N) = \partial y(x_N)/\partial y_0$.

Thus, for optimal step size, one has to keep

$$\frac{H^{-1}(x_j)e_j}{h_j} \simeq k,$$

a constant.

From this we also find that the propagated error of e_j at x_N is

$$h_j H(x_N)k,$$

and the total error at x_N due to the propagation of local error is estimated at

$$E \simeq \sum_{j=1}^{N} h_j H(x_N)k$$

$$= (x_N - x_0)H(x_N)k.$$

5.5 Application of the Lie Series Method to the Reflection Equation

In order to perform an integration in Eq.(4-3), we employed the Gauss-Legendre quadrature formula

$$\int_0^1 f(x)dx \simeq \sum_{k=1}^{N} c_k f(x_k),$$

where c_k are the Christoffel numbers, defined by

$$c_k = \int_0^1 \frac{P_N(x)dx}{(x-x_k)P_N'(x_k)}, \quad k = 1,2,\ldots, N,$$

and x_k are roots of Legendre polynomial of degree N, Eq.(4-3) is then replaced by the approximate equation

$$\frac{dr}{dx} \simeq \frac{1}{\gamma}\left[1+ \frac{1}{2} \sum_{k=1}^{N} \frac{c_k}{\mu_k''} r(x,\mu,\mu_k'')\right]\left[1+ \frac{1}{2} \sum_{k=1}^{N} \frac{c_k}{\mu_k'} r(x,\mu_k',\mu_0)\right] - \left(\frac{1}{\mu_0} + \frac{1}{\mu}\right)r \quad (5\text{-}64)$$

with the same initial condition,

$$r(0,\mu,\mu_0) = 0.$$

The sets $\{\mu_k''\}$ and $\{\mu_k'\}$ are the same. In Eq.(5-64) discretize μ and μ_0 by letting μ assume only the values μ_1', μ_2' ,...,μ_N' and μ_0 only the values $\mu_1'',\mu_1'',\ldots,\mu_N''$ and define

$$r_{ij}(x) = r(x,\mu_i',\mu_j'').$$

Eq.(5-64) then is replaced by the following set of N^2 nonlinear ordinary differential equations:

$$\frac{dr_{ij}}{dx} = \frac{1}{\gamma}\left[1 + \frac{1}{2}\sum_{k=1}^{N}\frac{c_k}{\mu_k''}r_{ik}\right]\left[1 + \frac{1}{2}\sum_{k=1}^{N}\frac{c_k}{\mu_k'}r_{kj}\right] - \left(\frac{1}{\mu_i'} + \frac{1}{\mu_j''}\right)r_{ij}\ , \qquad (5\text{-}65)$$

with the initial conditions

$$r_{ij}(0) = 0.$$

By the symmetry condition,

$$r_{ij}(x) = r_{ji}(x), \quad i,j = 1,2,\ldots, N.$$

This allows one to reduce the dimension of (5-65) from N^2 to $N(N+1)/2$.

In applying the Lie series perturbation method to Eq.(5-65), first three terms of a Taylor series expansion of the functions were taken as the solutions to the perturbed system, which has the same initial conditions as the given equations, and make use of it as a starting solutions in the iteration method, in which three terms of the Lie series expansion were used in each process as correction.

In order to compare the results of the Lie series method with that of the Runge-Kutta method given by Bellman, seven nodes were used in the Gauss-Legendre quadrature formula.

CHAPTER VI

RESULTS AND CONCLUSIONS

In this investigation calculations were made for $\gamma = 0.1$, 0.6, and 1.0. The results* for $\gamma = 0.1$ are in exact agreement with those from Bellman's Runge-Kutta method, and the results from $\gamma = 0.6$ and 1.0 deviate slightly or not at all (the maximum percentage deviation from Bellman's results is found to be less than - 0.02%).

No direct comparison of the speed of calculation for both methods has been made. But from indirect estimation, the iterative Lie series perturbation method is many times faster than the Runge-Kutta fourth-order method. The comparison is based on the following facts and assumptiom:

1. The speed ratio of UNIVAC 1108 to IBM 360/50 computers in solving a restricted-three-body-problem by the Lie series method is about 3.

2. The time for solving a two-dimensional reflection function, with five y-divisions, five polar angles, five azimuthal angles (125 equations), and 25 x-steps by the Runge-Kutta method is about one hour on UNIVAC 1107 computer[75]. It is about 1.663 sec./Eq.-step on UNIVAC 1107.

---

* The results from the computer output are the solutions of the symmetric functions $r(x,\mu_i,\mu_j)$. In order to compare with the results given by Bellman, we have to divided these figures by four times the cosine of angle of reflection.

3. The speed of UNIVAC 1107 and 1108 computers are assumed as the same.

4. The rate for solving a one-dimensional reflection function with seven polar angles, or 28 equations by the Lie series perturbation method is about 0.938 sec./Eq.-step on IBM 360/50 computer.

The iterative Lie series perturbation method can be operated with some flexibility. In addition to the calculation of the reflection function with three γ values at the same order of the method, the effect of other parameters on the accuracy of the results and on the computing time were also compared. These comparsions were (1) double precision vs. single precision, and (2) varying the order of the method.

Based on the three point approximate reflection function, the first three terms in Taylor series expansion were taken as first approximate solutions. Three terms in the Lie series expansion are used in each iteration as a correction, with $\gamma = 0.1$, with the thickness of the slab 0.6(0.6)3.0 mean free paths (mfp), and with the lower bound of local truncation errors of 10^{-8}. The results from single precision calculation tend to be smaller than that those from double precision calculation by the order of about 10^{-6}, as shown in Table 1. The computing time in double precision calculation is about 1.66 times that of single precision.

Thus, for a slab thickness of 3 mfp or less, a double precision calculation seems to be unnecessary.

The purpose of using double precision calculations is to reduce the rounding errors. Thus for a thick slab, say 20 mfp, and $\gamma = 1.0$, the differences in the results of double precision and single precision calculations still need to be investigated.

Table 2 shows the comparison of the results by varying the order of the method. These results are also from three-point approximate reflection functions, with $\gamma = 0.1$, the preset bound of local truncation errors are 10^{-8}. We see that oscillation occurs at almost every solution. In this case, the proportion of the computing time for the order of the method of 7, 10, 15, and 20 is 1 : 1.21 : 1.26 : 1.56.

The oscillation occurring in the solution can be reduced by tightening the error bound. Table 3 shows how the situation was improved by choosing a proper error bound for each method. It is because when we use the order of the method of p, and if the step size is on the order of 10^{-1}, then the truncation error involved in the solutions is on the order of $10^{-(p+1)}$. If the error bound we selected is greater than $10^{-(p+1)}$, than a bigger step size will be taken in the next step of calculation. This leads to a less accurate result, or causes the oscillation in the solutions.

In the actual computations, the step size often varies from 10^{-1} to 10^{-2}. Thus, for a given order of the method p, the truncation errors can be varied from the order of $10^{-(p+1)}$ to $10^{-2(p+1)}$. Because the error bound remains constant throughout the computation, small oscillations in the solutions are inevitable in the Lie series method.

The proportion of the computation time in the later case, for the order of the method of 7, 10, 15, and 20 is 1 : 1.38 : 1.69 : 2.11.

The computing time can be varied appreciably in the same order of the method. The order of the method is defined as $p \equiv m + s + 1$, here m is the order of the Taylor series expansion, and s is the order of the Lie series correction. Generally speaking, for a given order of the method, the more terms taken from the Taylor series, the better the starting solution we get, and the fewer terms needed in the Lie

* In case I, first 10 terms of the Taylor series were taken as the starting solutions, and first 4 terms of the Lie series were taken as the correction. In case II, first 11 terms of the Taylor series were taken as the starting solutions, and first 3 terms of the Lie series were taken as the correction. The computing time in the Case I and Case II are 0.5702 and 0.4375 second per step per equation respectively.

series correction process. Since it is easier to calculate the Taylor series than the Lie series, in the actual computation, it is favorable to take as many terms in the Taylor series as possible. For example, an order of the method of 15 (partial results are listed in Table 4), in one case, we use the first 11 terms in the Taylor series as a starting solution, and the first 3 terms in the Lie series as correction. The computing time is 0.4375 sec./step-Eq.; in another case, we use the first 10 terms in the Taylor series as starting solution, and the first 4 terms in the Lie series as correction. The computing time is 0.5702 sec./step-Eq. The ratio of the computing time for the two cases is 1.3. The differences in the computing time will widen if a higher order of quadrature formula is used, and if more terms of the Lie series are calculated, as one might expect.

The symmetrical property of the reflection function $r_{ij}(x)$ with respect to its angular arguments is best explained by the reciprocity property of transport function. In terms of the principle of reciprocity[12], the symmetrical reflection function can be explained as follows:

(1) The interchange of the direction of incidence and the direction of reflection of particles effects the interchange of the magnitude of source strength and the magnitude of the reflection function.

(2) For a given thickness of the slab, the component of the reflected flux normal to the slab surface in direction Ω due to a given strength of incident beam in direction Ω_0 is the same as the normal component of the flux of the reflected beam in the direction $-\Omega_0$ due to the same strength of the incident beam in the direction $-\Omega$.

Figs. 4 through 7 show the normalized reflection curves in the polar coordinate. Only two limiting cases for a given value of γ are plotted. These results are obtained from symmetrical reflection functions divided by four times the cosine of reflection angle, then normalized. An interesting characteristic common to these is that no matter what direction the incident particle may come from, the maximum reflection flux always occurs at the maximum reflection angle.

Figs. 8 and 9 show the typical normalized reflection curves, obtained by normalizing the symmetrical reflection functions. We see that for γ of 0.1 all the curves level off near the slab thickness of 3.0 mfp, and for γ of 0.6, the curves level off near the slab thickness of 4.0 mfp.

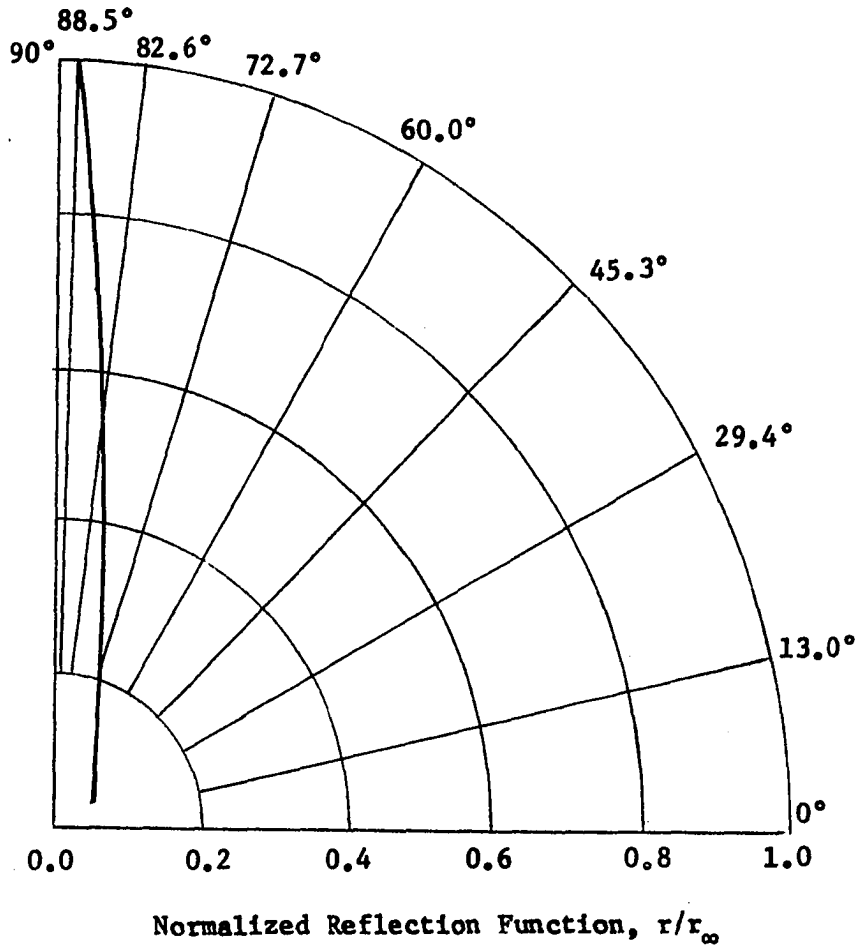

Fig. 4. Normalized Reflection Curve with Gamma = 0.1, the Angle of Incidence of 88.5°, and the Slab Thickness of 0.1 mfp.

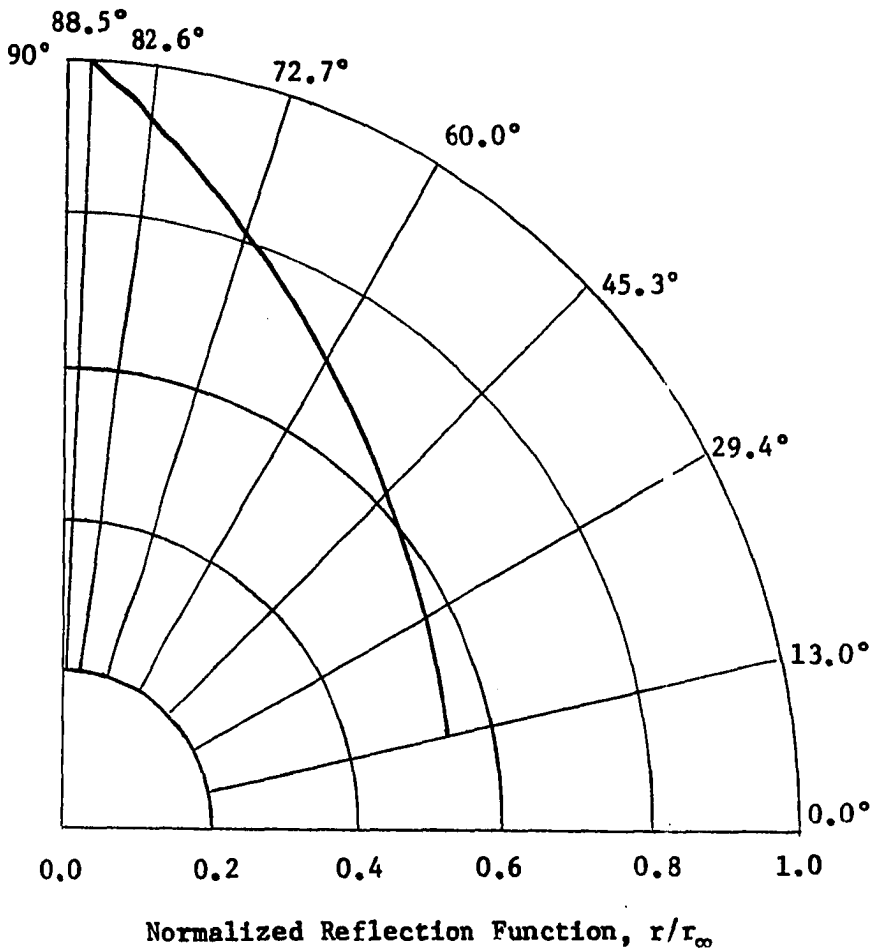

Fig. 5. Normalized Reflection Curve with Gamma = 0.1, the Angle of Incidence of 13.0°, and the Slab Thickness of 3.0 mfp.

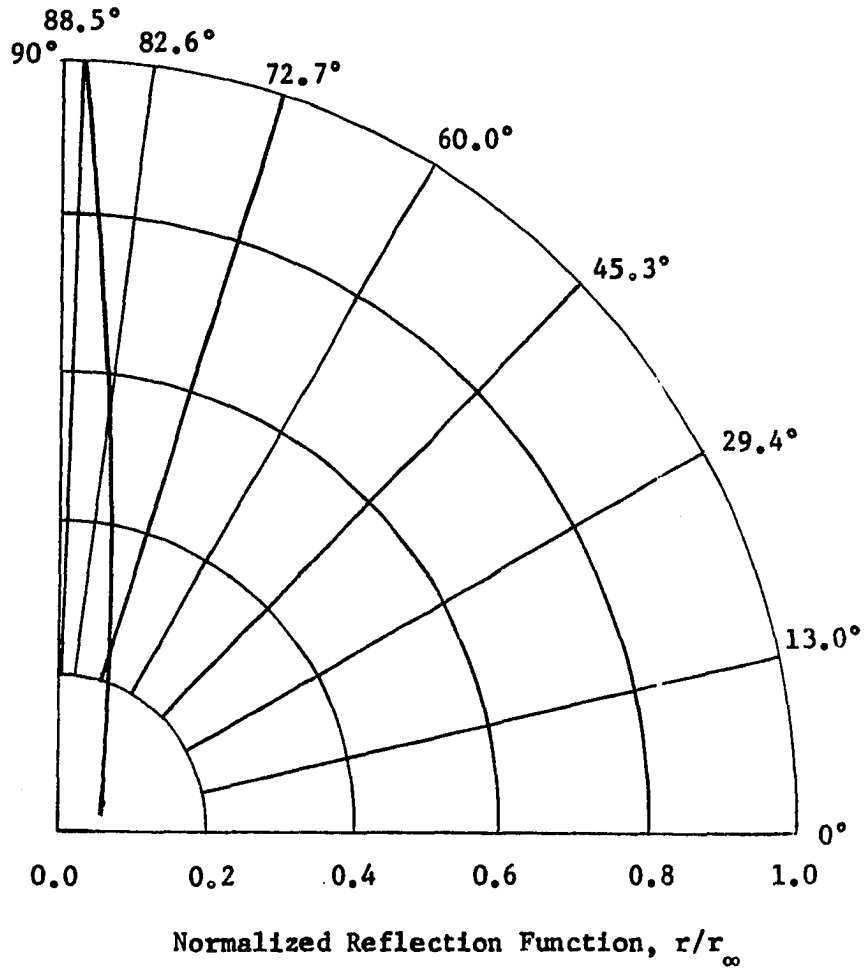

Fig. 6. Normalized Reflection Curve with Gamma = 0.6, the Angle of Incidence of 88.5°, and the Slab Thickness of 0.1 mfp.

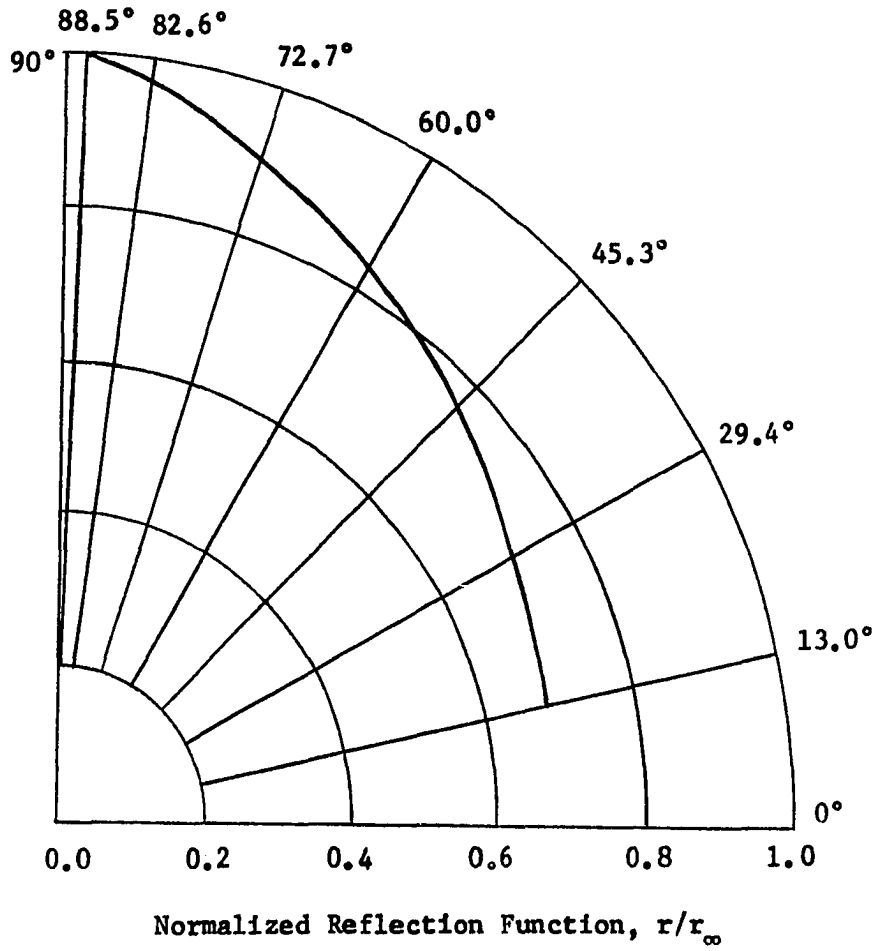

Fig. 7. Normalized Reflection Curve with Gamma = 0.6, the Angle of Incidence of 13.0°, and the Slab Thickness of 3.0 mfp.

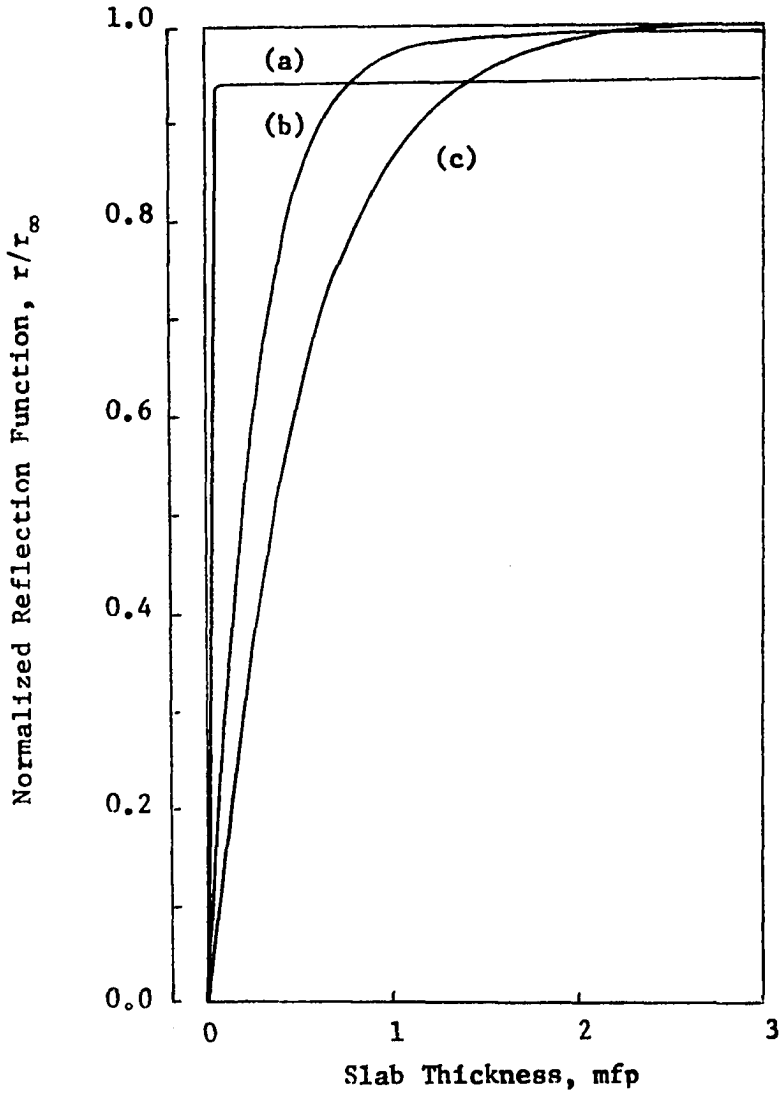

Fig. 8. Normalized Reflection Curves with Gamma = 0.1, and the Angle of Incidence/Angle of Reflection are: (a) 13.0°/13.0°, (b) 60.0°/60.0°, and (c) 88.5°/88.5°.

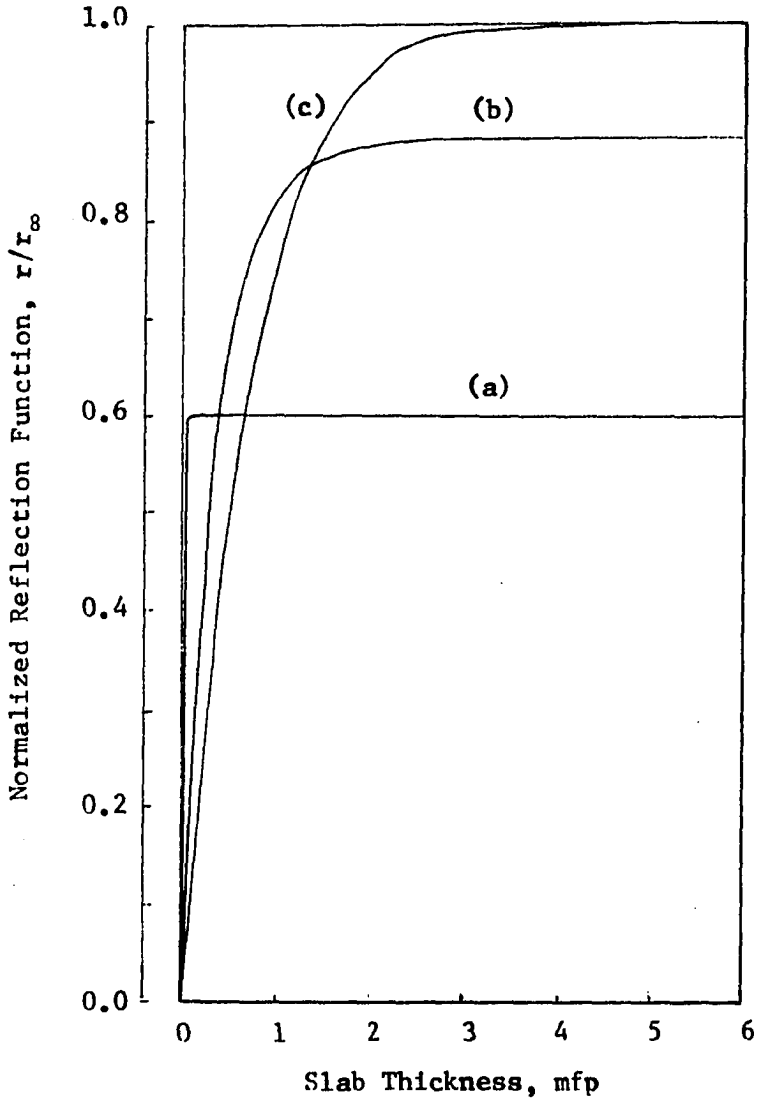

Fig. 9. Normalized Reflection Curves with Gamma = 0.6, and the Angle of Incidence/Angle of Reflection are: (a) 13.0°/13.0°, (b) 60.0°/60.0°, and (c) 88.5°/88.5°.

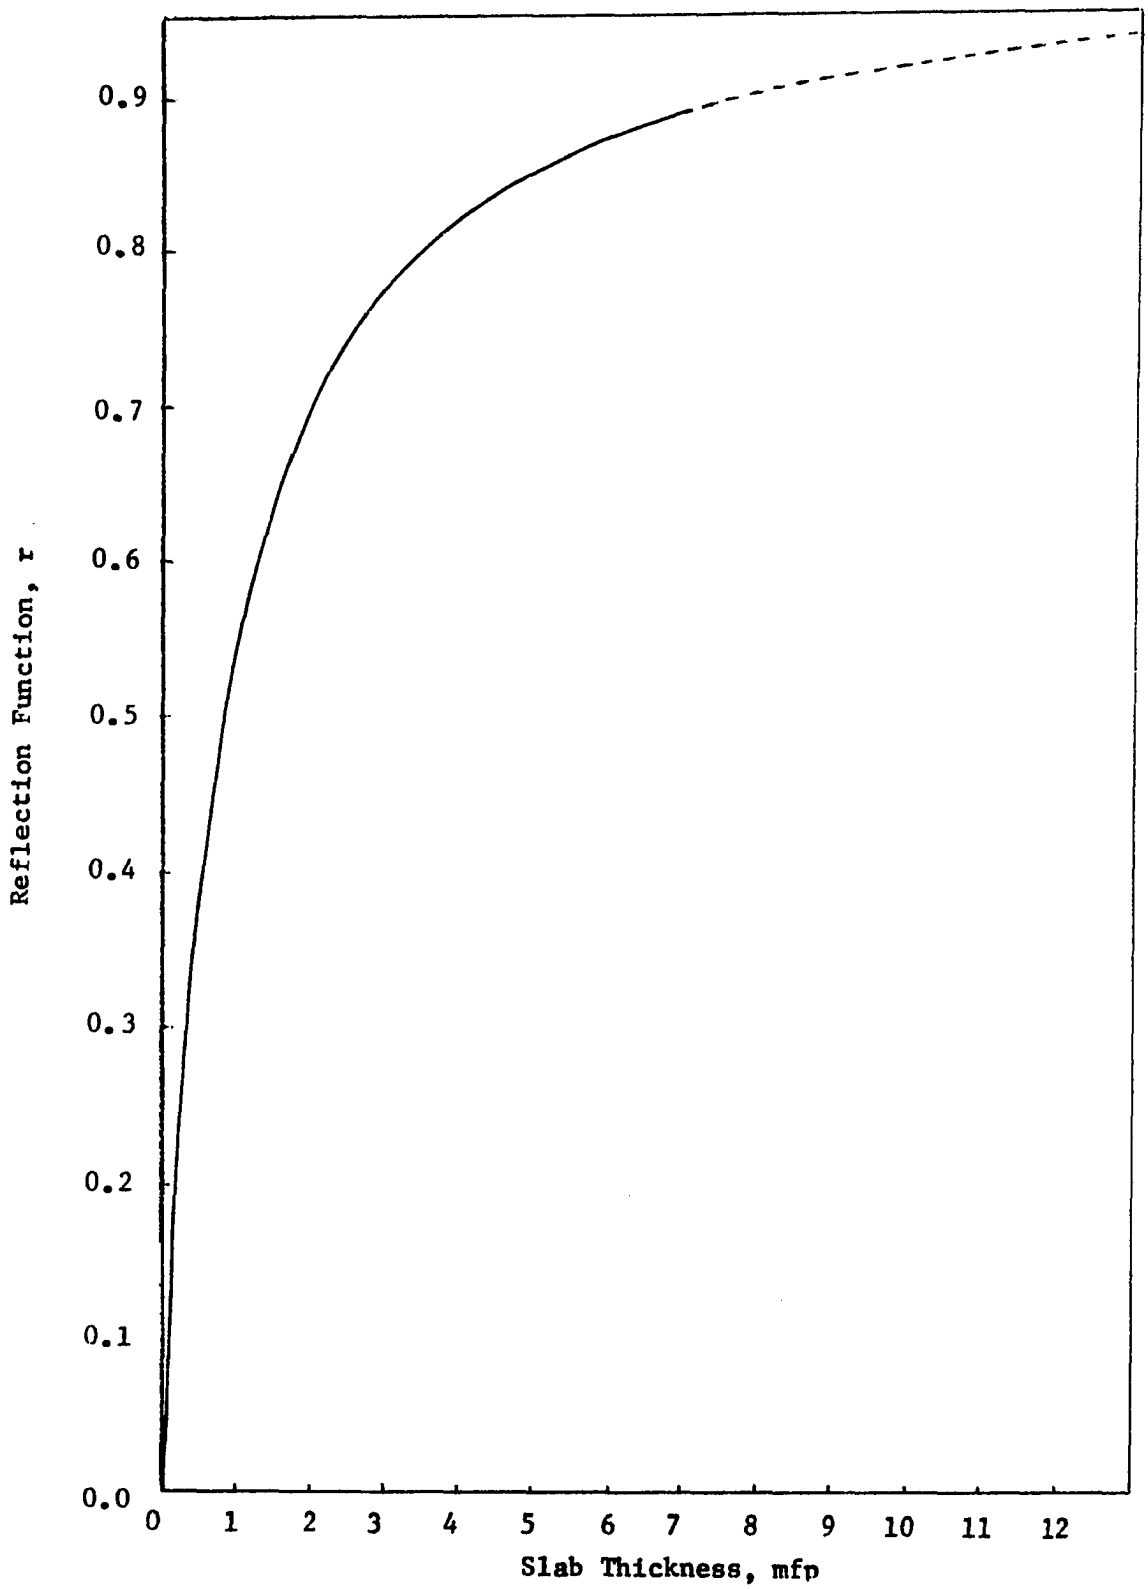

Fig. 10. Reflection Curve with Gamma = 1.0, and the Angle of Incidence = Angle of Reflection = 60.0°.

From these results the following conclusions are reached:

1. The iterative Lie series perturbation method is effective in solving the invariant imbedding transport equations. It can give results of arbitrarily high accuracy by simply increasing the order of the method, provided that a sufficient amount of time is expended on their calculation. Also, because of the rapid convergence of this method, the same accuracy can be obtained as with the Runge-Kutta method, at much faster speed. But in the Lie series method, a bigger computer memory is required(248K vs. 32K).

2. We cannot estimate the rounding errors involved in the calculation by the iterative Lie series method, but decreases in rounding errors are expected with the variable step size controls in comparison with the fixed step size calculations.

3. The invariant imbedding reflection functions satisfy a reciprocity relation.

4. The reflection function increases with increasing angle between the direction of normal to the slab and the direction of reflection while the other paramters are fixed.

5. For γ less than or equal to 0.6, a slab thickness of 4.0 mfp is essentialy equivalent to infinite thickness.

CHAPTER VII

RECOMMENDATIONS

1. The effectiveness of the Lie series perturbation method in solving the one-dimensional invariant imbedding reflection function implies that it can be applied equally well to similar problem of greater complexity. Thus, to gain more knowledge of the usefulness of the Lie series method in invariant imbedding transport calculations, it is worthwhile to recalculate the two-dimensional problem and the problem of gamma ray penetration.

2. The invariant imbedding formulation of the transport equation for cylindrical geometry with finite height has not been done yet. Since it is of practical importance, any efforts to derive the transport equation for this geometry should be encouraged.

3. One advantage of iterative Lie series perturbation method, as indicated by the transfer matrix, is its capability to calculate the total truncation error. There is no existing numerical method to estimate the total truncation error easily for the problem of this complexity. Thus if one is interested in knowing the total truncation error in his solution he may start from the Lie series perturbation method.

4. Although the Lie series perturbation method allows easy estimation of the truncation error, it is even better if one can confine the error to a certain interval. Such a method has been proposed by Moore[114], and a

computer program has been written by Ladner and Yohe[117]. In order to find a better numerical method to solve the invariant imbedding transport equation, the method of interval analysis should be investigated.

5. According to Bellman's result, for γ equal to 1.0, in a 20 mfp slab, the reflection function decreases with increasing the angle of reflection. The reason for the inversion of this property is not clear, a further study seems to be needed.

Appendix A

Description and Listing of the Computer Programs

The Lie series computer programs were originally written by Mathematics Research Center, The University of Wisconsin[116], in Fortran V, for UNIVAC 1108 computer. Because of extreme machine dependence of the subroutine NXTCHR, it was completely rewritten to fit IBM 360/50 computer. Others were also modified to meet our purpose.

Subroutines MMULT and INVERT in the original programs were replaced by subroutines GMPRD and MINV of IBM system/360 Scientific Subroutine Package Version III, respectively.

The stacking of the deck is as follows:

1. Main program.
2. Sub-programs.
3. Fixed input data: Quadrature coefficients A and C.
4. System of differential equations.
5. Variable parameters:

a. Order of the Taylor series expansion (MM), order of the Lie series correction (LL), number of nodes in the Gauss quadrature formula (KK), number of equations (NN).

b. Switch for the table control (ITAB), number of abscissas (NNTAB), switch for step size control (ISTV), switch for intermediate step values outputs (NZWI), switch for the calculation of the transfer matrix (IJAC), and the order for the calculation of the transfer matrix (MMJ).

c. Initial step size (STH), initial value of independent variable (XX0), and the initial values of dependent variables (YY0(NN)).

d. Bounds on local truncation errors (GAM(NN)).

e. The lower tolerance bound (ETA1) and the upper tolerance bound (ETA2) for the error ratio.

f. The abscissas at which the results should be printed out (TAB(NN)).

or f'. The table-difference (DTAB), in case a constant step size is choosen.

and g. A signal of the end of the program (any negative MM).

```
C      MAIN PROGRAM
C      THE MAIN PROGRAM MANAGES THE INPUT, THE OUTPUT, THE STEP SIZE CONTROL
C      AND THE TABLE LOOP.
C
C      LIST OF PRINCIPAL VARIABLES
C
C MM   THE ORDER OF THE APPROX. SOLUTION OR THE NUMBER OF TERMS IN TAYLOR SERIES
C      (0≤MM≤5).
C LL   THE ORDER OF THE LIE SERIES CORRECTION (0≤LL≤10).
C KK   THE NUMBER OF NODES IN THE GAUSS-QUADRATURE FORMULA (1≤KK≤6).
C NN   THE NUMBER OF DEPENDENT VARIABLES IN THE SYSTEM OF DIFFERENTIAL EQS.
C ITAB SWITCH FOR THE WANTED TABLE
C      ITAB¬=0: THE SOLUTIONS SHOULD BE PRINTED OUT AT DIFFERENT ABSCISSAS TAB(1)
C      .......TAB(NNTAB).
C      ITAB=0: THE SOLUTIONS SHOULD BE PRINTED OUT AT EQUIDISTANT ABSCISSAS.
C      AND ONLY THE TABLE-DIFFERENCE DTAB WILL BE READ IN LATER.
C NNTAB NUMBER OF ABSCISSAS TAB(I)
C TAB(I)=X(I) THE ABSCISSAS AT WHICH THE RESULTS SHOULD BE PRINTED OUT.
C ISTV SWITCH FOR THE STEP SIZE CONTROL
C      ISTV=0: CONSTANT STEP SIZE. THE PROGRAM WILL USE THE STEP SIZE STH WHICH
C         IS READ IN LATER.
C      ISTV=1: STEP SIZE CONTROL IS USED WHICH KEEPS THE LOCAL TRUNCATION ERRORS
C         BELOW BOUNDS  WHICH ARE ALSO READ IN LATER.
C      ISTV=2: OPTIMAL STEP SIZE CONTROL USING THE CONNECTION MATRIX (IN THIS
C         CASE, IJAC=1).
C NZWI SWITCH FOR INTERMEDIATE STEP VALUES OUTPUTS (IN ADDITION TO THOSE OF THE
C         TABLE ABSCISSAS)
C      NZWI=0: NO  INTERMEDIATE RESULTS ARE PRINTED OUT.
C      NZWI=J>0: THE RESULTS AFTER EACH J-TH STEP ARE PRINTED OUT.
C IJAC SWITCH FOR THE CALCULATION OF THE CONNECTION MATRIX
C      IJAC=0: THE MATRIX IS NOT CALCULATED.
C      IJAC=1: THE MATRIX IS CALCULATED AND PRINTED OUT TOGETHER WITH THE
C         OTHER RESULTS.
C MMJ  THE ORDER FOR THE CALCULATION OF THE CONNECTION MATRIX (0≤MMJ≤MM).
C STH  THE CURRENT STEP SIZE H. IF ISTV¬=0, STH IS USED AS THE INITIAL APPROX.
C      FOR THE ITERATIVE CALCULATION OF A SUITABLE STEP SIZE.
```

```
C STHC THE NEW STEP SIZE. (=STH*(1/ETA)**(1/(M+L+2))
C                          IF ETA≦ETA2, UPPER TOLERANCE BOUND.
C                           =STH*(ZETA-ZETA1*ETA)
C                          IF ETA<ETA1, THE LOWER TOLERANCE BOUND).
C XX0 THE INITIAL POINT OF THE INDEPENDENT VARIABLE X.
C YY0(N) THE INITIAL VALUES FOR THE SOLUTIONS YI.
C R(I) THE LOCAL TRUNCATION ERRORS OR THE LOCAL ERROR ESTIMATES.
C GAM(N) UPPER BOUND ON THE LOCAL TRUNCATION ERRORS (REMINDERS).
C ETA THE ERROR RATIO(=|R(I)|/GAM(I)).
C ETA1 THE LOWER TOLERANCE BOUND. (0<ETA1<1).
C ETA2 THE UPPER TOLERANCE BOUND. (FROM 1.1 TO 2.0).
C DTAB THE TABLE-DIFFERENCE OR CONSTANT STEP SIZE H.
C HJ   THE CONNECTION MATRIX.
C IZ   THE NUMBER OF THE STEPS, WHICH ARE USED FOR THE CONTINUATION OF THE
C      SOLUTION.
C IZI THE NUMBER OF THE REPEATED STEPS, WHICH WERE NOT USED FOR THE CONTINUATION
C      BECAUSE THE CORRESPONDING TRUNCATION ERRORS WERE ABOVE THE ALLOWED BOUNDS.
C ISW THE SWITCH. IF ISW=1, THE SUBROUTINES CALCULATE THE MU-TH ORDER TAYLOR
C      COEFFICIENT.
C      IF ISW=2, THE COEFFICIENTS OF GROEBNER'S FORMULA ARE CALCULATED.
C YHAT(I) THE TAYLOR SERIES APPROXIMATION.
C YQUER(I) THE LIE SERIES SOLUTION.
C CJ(I,K) THE LOCAL CONNECTION MATRIX WITH ORDER MMJ.

0001   SUBROUTIN- CONCHK (NUMCON,LEFT,RIGHT,CCMMUT)
C      CONCHK IS USED TO OBTAIN A CERTAIN AMOUNT OF LOCAL OPTIMIZATION IN THE
C      CODE BEING PRODUCED. IT IS CALLED BEFORE GENERATING CODE FOR ANY BINARY
C      OPERATOR.
C    NUMCON=3 IF BOTH OPERANDS ARE CONSTANTS. THE OPERATION IS PERFORMED AT
C      COMPILE TIME BY THE APPROPRIATE GENERATOR.
C    NUMCON=1 IF NEITHER OPERAND IS A CONSTANT.
C    NUMCON=2 IF THE RIGHT OPERAND IS A CONSTANT, OR  IF THE LEFT OPERAND IS A
C      CONSTANT AND THE OPERATOR IS COMMUTATIVE. IN BOTH CASE A MORE EFFICIENT
C      OPERATION CODE CAN THEN BE EMITTED. E.G. A PODK   INSTEAD OF A PROD.
C    IF LEFT OPERAND IS A CONSTANT AND THE OPERATOR IS NOT  COMMUTATIVE, THEN THE
C      CONSTANT IS ASSIGNED PERMANENTLY TO A CELL IN THE TARRAY AND TREATED AS A
C      VARIABLE.
