## PREFACE

The purpose of this study is to present the basis design equations required to size a reflux condenser. A computer program is also written to handle the condensation of both a pure vapor and a multicomponent vapor.

Two examples are also presented. The results look reasonable, but lack of experimental data prevents a more quantitative test of the program.

I wish to express my sincere thanks to Dr. Kenneth J. Bell for his advice and guidance and to the School of Chemical Engineering for the financial support offered to me.

I also thank Mr. Suresh Balakrishnan and Mr. Roop Kumar for their help and encouragement. Finally, my thanks to Ms. Deborah Bryan for typing my thesis in such a short period of time.

## NOMENCLATURE

A	cross sectional area, $\text{ft}^2$
a	acceleration force field, $\text{ft}^2/\text{hr}^2$
$b_1$	numerical coefficient used in evaluating heat transfer coefficient, dimensionless
B	constant relating interfacial liquid velocity throughout the condensate film, dimensionless
$C_p$	specific heat, $\text{Btu}/\text{lbm } ^\circ\text{F}$
$dQ_{sv}, dQ_T$	local differential values of sensible load and total heat load, respectively, $\text{Btu}/\text{hr}$
D	inside tube diameter, inches
$D_c$	critical tube diameter, inches
f	shear stress multiplied by $g_c$ , $\text{lbm}/\text{ft}\text{-hr}^2$
FC	fraction condensed, dimensionless
$F_o$	wall shear stress multiplied by $g_c$ , $\text{lbm}/\text{ft}\text{-hr}^2$
Fr	Froude number based on total flow rate and local densities, dimensionless
$F_1, F_2$	correlation factors defined in equations 2.29 and 2.31, dimensionless
G	superficial vapor mass flux (or mass velocity), $\text{lbm}/\text{ft hr}^2$
g	acceleration of gravity, $\text{ft}/\text{hr}^2$
$g_c$	conversion factor $4.175 \times 10^8$ , $\text{lbm ft}/\text{lb f hr}^2$
$\overline{h}_c$	average heat transfer coefficient, $\text{Btu}/\text{hr ft}^2 ^\circ\text{F}$

$h_c(z)$	local heat transfer coefficient, Btu/hr ft <sup>2</sup> °F
$h_{sv}$	vapor phase heat transfer coefficient, Btu/hr ft <sup>2</sup> °F
$k$	thermal conductivity, Btu/hr ft °F
$k_i$	equilibrium constant, dimensionless
$L$	superficial liquid mass flow rate, lbm/hr ft <sup>2</sup>
$L_T$	length of tube, ft
$L/F$	liquid to feed ratio, dimensionless
$M_i$	mole fraction in feed of component, dimensionless
$N_{tubes}$	number of tubes, dimensionless
$OD$	outer tube diameter, inches
$P$	pressure, psia
$Pr_\ell$	Prandtl number, dimensionless
$q''$	heat flux, Btu/hr ft <sup>2</sup>
$Q_T$	heat recovered per tube, Btu/hr
$Q_{Total}$	total heat recovered in all tubes, Btu/hr
$Re_c$	condensate Reynolds number, dimensionless
$Re_{LT}$	Reynolds number of the condensate at the bottom of the tube, dimensionless
$Re_{Lz}$	local Reynolds number of the condensate at any point along the tube, dimensionless
$Re_T$	Reynolds number based on total flow rate and local vapor density (Eq. 3.6), dimensionless
$R_{fi}, R_{fo}$	inside and outside fouling resistances, respectively, hr ft <sup>2</sup> °F/Btu
$S$	circumference, ft
$T$	temperature, °F

$T_1, T_2$	temperature of the coolant at the inlet and outlet, respectively, °F
$U_i$	overall heat transfer coefficient from vapor liquid interface to the coolant, Btu/hr ft <sup>2</sup> °F
$u^*$	frictional velocity, ft/sec
$V_f$	flooding velocity, ft/sec
$V_\ell$	mean liquid film velocity, ft/sec
$V_{\ell i}$	interfacial velocity, ft/sec
$V_v$	vapor velocity, ft/sec
$V_{v, o}$	outlet vapor velocity, ft/sec
$W$	mass flow rate, lbm/hr
$x$	local quality, dimensionless
$x_i$	mole fraction of liquid of component i, dimensionless
$y_i$	mole fraction of vapor of component i, dimensionless
$\Delta z$	length increment, ft
$Z$	ratio of $\frac{dQ_{sv}}{dQ_T}$ , dimensionless

$\Delta$	difference, finite
$\epsilon$	small number
$\eta$	force due to gravity on liquid, $\text{lb}_f/\text{ft}^2$
$\theta$	angle
$\lambda$	latent heat of condensation, Btu/lbm
$\mu$	viscosity, absolute, lbm/hr ft
$\rho$	density, $\text{lbm}/\text{ft}^3$
$\sigma$	surface tension, dynes/cm
	term in equation 2.3, dimensionless
$\tau_i$	interfacial shear stress, $\text{lb}_f/\text{ft}^2$
$\tau_o$	wall shear stress, $\text{lb}_f/\text{ft}^2$

## CHAPTER I

### INTRODUCTION

Condensation occurs when a vapor comes in contact with a surface whose temperature is below the saturation temperature at the existing partial pressure of the vapor. However, in case of multi-component condensation, the dew-point temperature must be used and it should be noted that the composition of the condensate formed is different from the composition of the vapor mixture at the same temperature and total pressure.

Vertical condensers with upward flow of vapor have not been as thoroughly investigated as those with downward flow of vapor. But sometimes it is necessary to maintain a liquid mixture at a given temperature, while carrying on an exothermic chemical reaction. In order to do so, a volatile liquid can be vaporized in the reactor and returned as a liquid at a continuous rate from the reflux condenser (Figure 1). Pressure and therefore the temperature in the reactor can be controlled by controlling the coolant flow rate and temperature to the condenser.

One of the major problems in a reflux or knock-back condenser (Figure 2) is the flooding of tubes. When the vapor flow is counter-current to the condensate flow, the following effects are observed (1). Figures 3a-3e show the changes taking place in a tube.

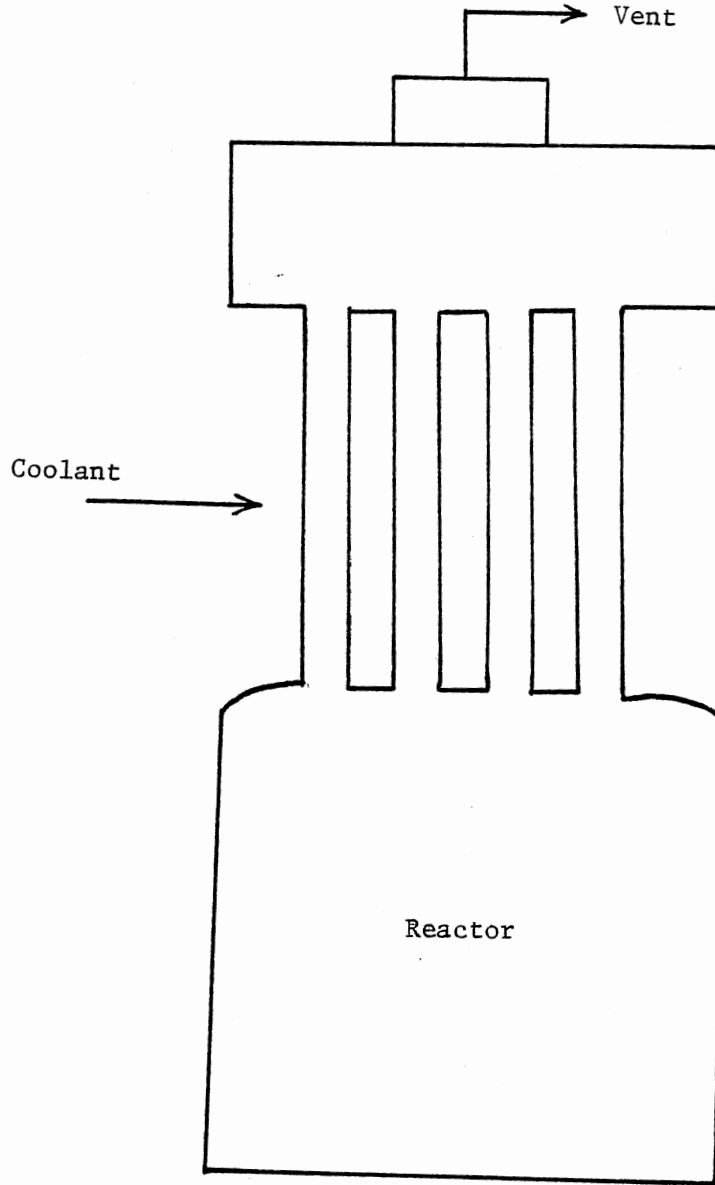

Figure 1. Reflux Condensation.

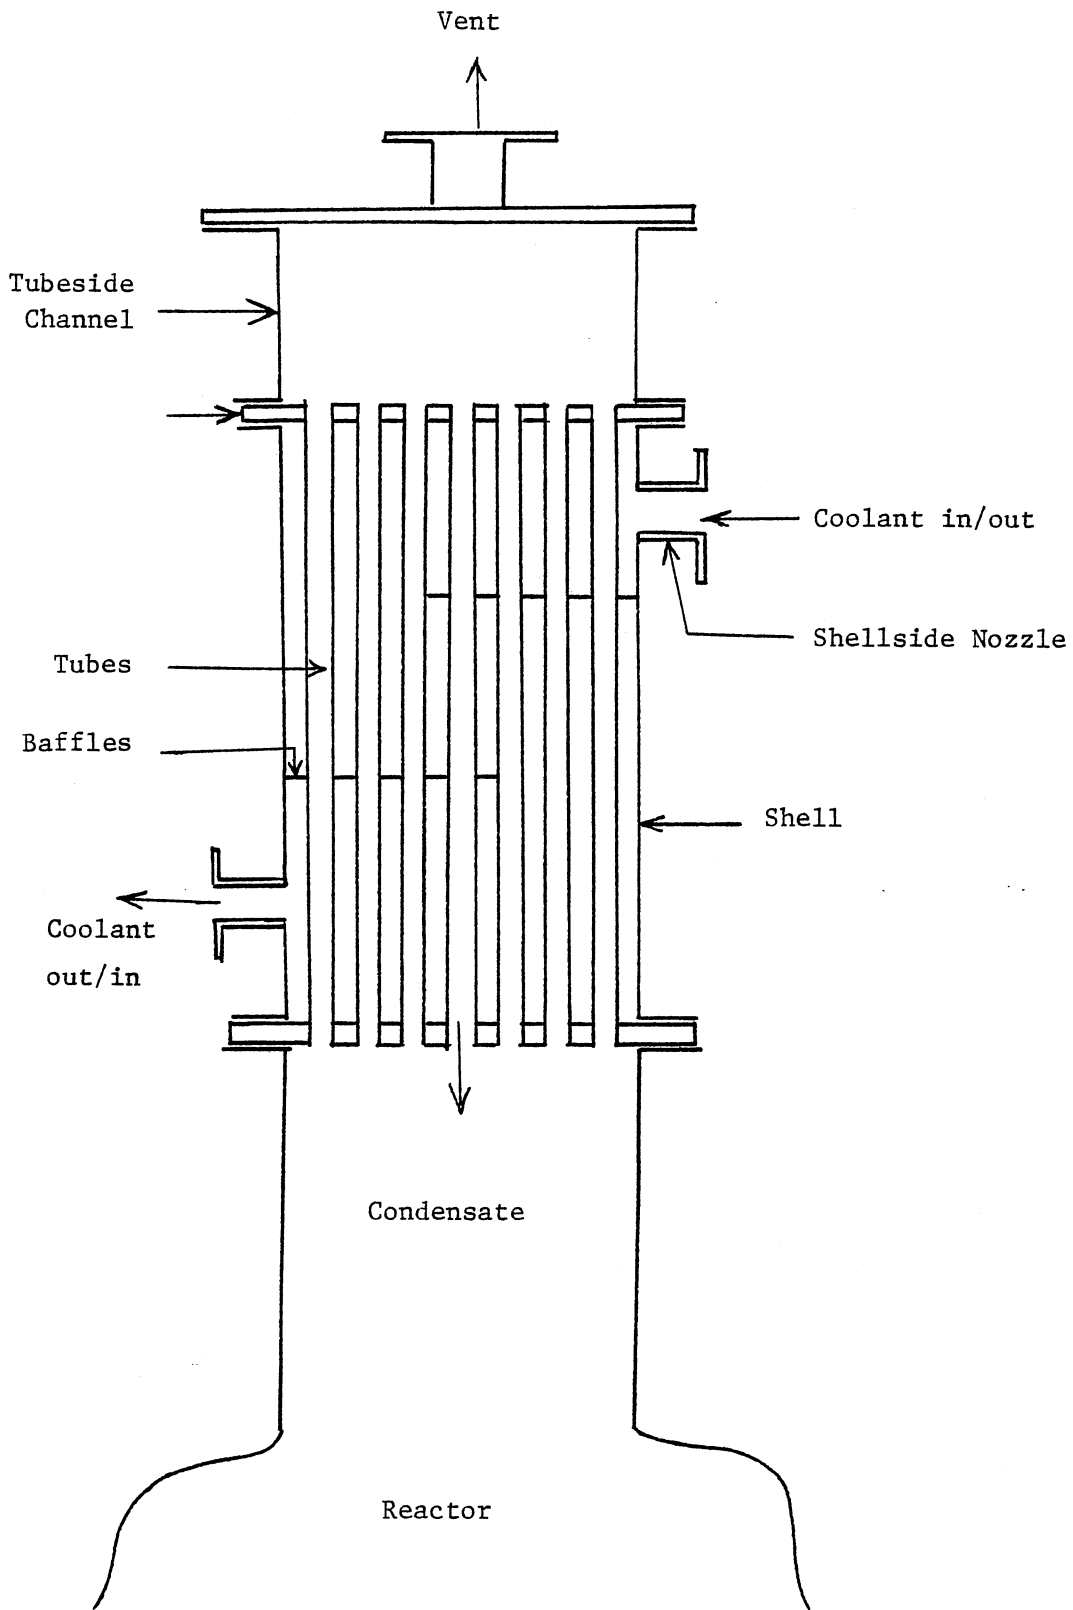

Figure 1. A Reflux Condenser

1. At low vapor velocities, the condensate runs down the walls of the tubes, thus giving reflux operation (Figure 3.a).
2. Increase of vapor velocity will result in the appearance of waves, especially near the inlet. This is because of the appearance of early turbulence at high vapor velocities (Figure 3.b).
3. Further increase in the vapor velocity causes the waves to bridge across the tube, but the flux rate remains constant (Figure 3.c).
4. The flooding point is said to have reached when the vapor velocity is high enough to eject the liquid out of the tube from the top. A dramatic rise in the pressure drop will occur as a result (Figure 3.c).
5. Further increase in the vapor flow will result in a climbing film annular flow (Figure 3.e).

In general, it is necessary to operate below the flooding velocity in order to avoid undesirable pressure fluctuations. Several correlations have been proposed to calculate the flooding velocity. The highest liquid and gas rates occur at the entrance of the tubes in a reflux condenser and hence, the flooding point is at the inlet (Figure 4).

English et al. (2) showed experimentally that a taper on the tube  
→ { end permits higher vapor rates to the exchanger before flooding takes  
place.

The purpose of this study is to outline the basic design equations required to size a reflux condenser. First, the flooding point is computed, followed by mass and heat balance. The method of calculating the heat transfer coefficient will be discussed.

In case of condensation of multicomponent mixtures, the approximate design procedure as outlined by Bell and Ghaly (3) will be used. A

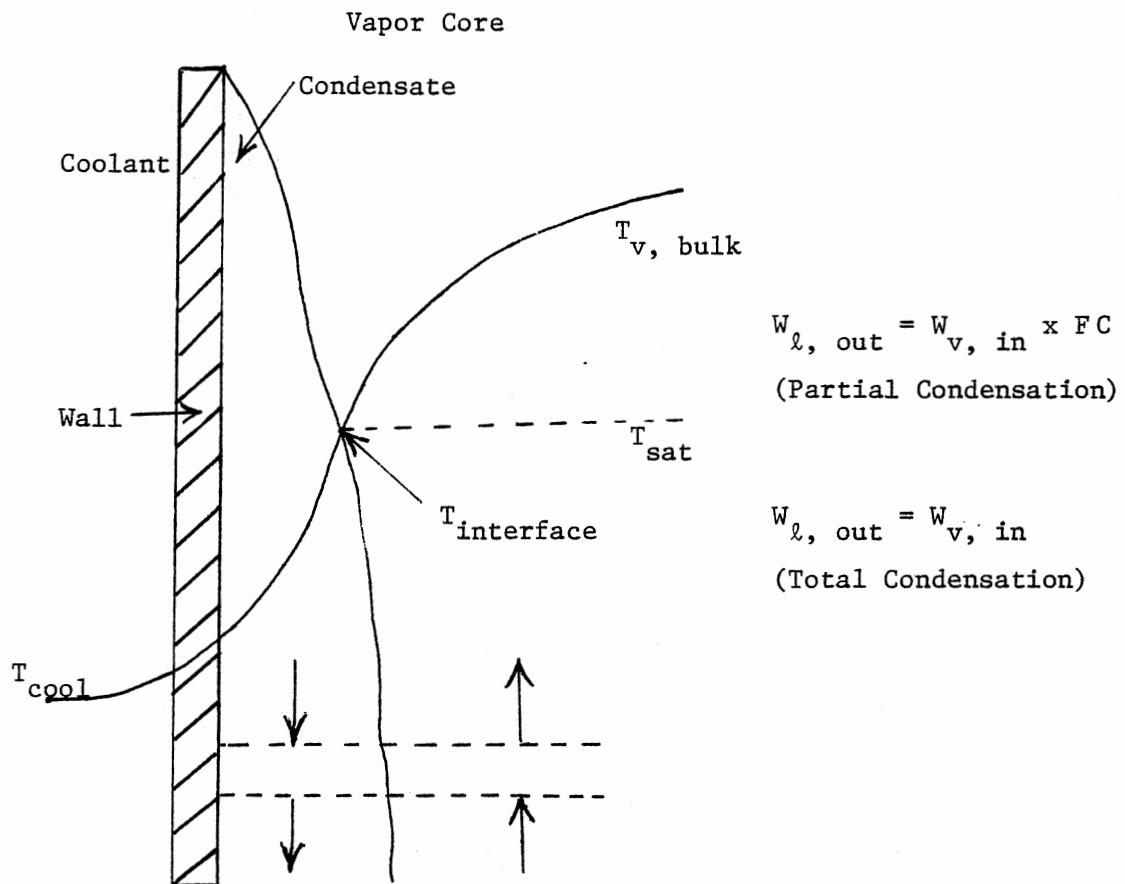

Figure 4. Flow Rates at Inlet.

computer program to handle the condensation of both a pure vapor as well as a multicomponent vapor is presented in Appendix B. The program  handles saturated vapors only. In the case of multicomponent condensation, the thermodynamic and physical properties are read as input data. They are calculated using the GPA\*SIM (4) program.

## CHAPTER II

### LITERATURE REVIEW

Filmwise condensation on a vertical surface was first studied by Nusselt (5). Although the original work was published in German, the details of his analysis are readily available in a number of books, e.g., Jakob (6). The details of the analysis will not be presented here. Only the important results will be mentioned.

One of the assumptions that Nusselt made was that even in the presence of high vapor velocities the entire condensate film remained in laminar flow. This will not affect the heat transfer coefficient strongly as long as the velocities are low (laminar region). However, in case of vapor shear, turbulence may appear at Reynolds number as low as 250-300 as reported by Carpenter and Colburn (7).

In the absence of vapor shear, the Nusselt Equation for the average condensate heat transfer coefficient is:

$$\bar{h}_c = 1.47 \left[ \frac{k_\ell^3 \rho_\ell (\rho_\ell - \rho_v) g}{\mu_\ell^2} \right]^{1/3} Re_c^{-1/3} \quad (2.1)$$

In the present model, the point equation is used.

$$h_c(z) = \left( \frac{k_\ell^3 \rho_\ell (\rho_\ell - \rho_v) \lambda g}{4\mu_\ell (T_{sat} - T_w) z} \right)^{1/4} \quad (2.2)$$

Condensation heat transfer coefficients for turbulent flow were studied by Kirkbride (8), but Colburn (9) contributed a more fundamental analysis for the mean coefficient which is generally represented in graphical form (Figure 5). The break at a condensate Reynolds Number of about 2100 shows the point at which the film is presumed to become turbulent.

Dukler (10) developed new equations for velocity and temperature distribution based on the expressions proposed by Deissler (11) for the eddy diffusivity for momentum and heat. This accounted for turbulent fluctuations close to the wall. His equations require numerical solutions with the aid of a computer. [Although he developed his model for the case of cocurrent down flow of vapor and liquid, it can be modified for countercurrent-flow cases.] This can be done by taking negative values of the parameter  $\beta$  as defined by Dukler (Equation 2.3).  $\beta$  represents the forces due to interfacial shear and  $\eta$  represents the force due to gravity acting on the liquid.

$$\sigma^3 + \frac{\beta}{\eta^{2/3}} \sigma^2 - 1 = 0 \quad (2.3)$$

$$\beta = \frac{Fr \, g_l^{1/3} \, \rho_l^{2/3}}{2\mu_l^{2/3}} \quad (2.4)$$

The shear stress distribution is given by:

$$\frac{\tau}{\tau_o} = 1 - \frac{\sigma^3}{\eta} y^+ \quad (2.5)$$

$$\text{where } y^+ = (u^* y / \nu) \quad (2.6)$$

and  $u^*$  is usually called the friction velocity

$$u^* = \left( \frac{\tau_o \, g_c}{\rho} \right)^{1/2} \quad (2.7)$$

Figure 5. Correlation for Condensation on a Vertical Surface - No Vapor Shear. (9)

Average condensing heat transfer coefficients were calculated from the point values and the results obtained agree with Nusselt's values in the Nusselt region and approximately agree with Colburn's equation in the turbulent region. Figures 6 and 7 show the average heat transfer coefficients obtained from Dukler's analysis for the case of no interfacial shear and for the case of positive interfacial shear, respectively. In both cases, Prandtl number is equal to 1.0.

The equation governing Figure 6 is

$$\bar{h}_c \left( \frac{\mu_\ell^2}{\rho_\ell g k_\ell^3} \right)^{1/3} = \int_0^{Re_{LT}} \frac{Re_{LT}}{h_c(z) \left( \frac{\mu_\ell^2}{\rho_\ell g k_\ell^3} \right)^{1/3}} dRe_{Lz} \quad (2.8)$$

where

$Re_{LT}$  = Reynolds number of the condensate at the bottom of the tube

$Re_{Lz}$  = Local Reynolds number at any point along the tube.

However, Equation 2.8 cannot be used as such for the case with interfacial shear because  $\beta$  varies due to the variation in the pressure gradient. Hence, Dukler developed a new relation for  $\beta$ .

$$\beta = A (Re_{LT} - Re_{Lz})^{1/4} Re_{Lz}^{0.4} \quad (2.9)$$

$$A = \frac{0.25 \mu_\ell^{1.173} \mu_v^{0.16}}{g^{2/3} D^2 \rho_\ell^{0.443} \rho_v^{0.78}} \quad (2.10)$$

Then a plot of local Reynolds number  $Re_c$ , vs. the corresponding local coefficient term is made and the average coefficient is obtained by integrating the same expression as before.

Figure 6. Average Coefficient, No Interfacial Shear. (10)

Figure 7. Average Coefficient for  $Pr = 1.0$  (10)

Several objections were raised to Dukler's analysis (12).

- a. The velocity distribution he used was obtained from experiments in pipes with a different shear stress distribution.
- b. For  $y^+$  greater than 20, the molecular conductivity term is neglected with respect to eddy conductivity.

Although the above discrepancies are overcome in the analysis presented by Kunz and Yerazunis (13) their results do not vary very much from those of Dukler's.

Jakob, et al. (6) considered only the case of downward flowing vapor. They conducted experiments in a vertical condenser tube. The results obtained are shown in Figures 8 and 9. They are a result of 171 experiments with saturated steam at  $100^{\circ}\text{C}$  and  $325^{\circ}\text{C}$ , atmospheric pressure, and with an entrance velocity of the vapor,  $V_v$ , from 10 to 80 m/sec. The heat flux  $q''$  is plotted versus  $(T_{\text{sat}} - T_w)$  with  $V_v$  as the parameter. The conclusions that they drew were:

1. If the temperature difference is large, i.e.,  $(T_{\text{sat}} - T_w)$  is large, then the heat transfer is always larger than that predicted by Nusselt's theory. This could be due to the dropwise condensation on the vapor end of the cooling surface which accounts for more heat transmitted on the top of the tube, or possibly due to turbulent films (due to significant vapor shear effects).
2. For small values of temperature difference, the experiments with saturated steam resulted in smaller values of heat transferred than those predicted by Nusselt's theory. This is probably due to some air trapped in the tube.

Figure 8. Heat Transfer by Condensation of Saturated Steam at Atmospheric Pressure. (6)

Figure 9. Heat Transfer by Condensation of Superheated Steam at Atmospheric Pressure and  $325^{\circ}\text{C}$ . (6)

The empirical equation which Jakob et al. (6) recommend to represent their experimental results are:

1. Saturated Steam

$$q'' = 2.713(3400 + 100 V_{v, o}) (T_{\text{sat}} - T_w) (1.21/L)^{1/3} \quad (2.11)$$

2. Superheated Steam

$$q'' = 2.713 (3500 + 51 V_{v, o}) (T_{\text{sat}} - T_w) (1.21/L)^{1/3} \quad (2.12)$$

where  $q''$  is Btu/hr ft<sup>2</sup>.

As mentioned earlier, Carpenter and Colburn (7) studied vapor shear effects, and they found that the heat transfer coefficients were considerably larger than those obtained in the absence of vapor shear. The major force acting on the condensate film is the interfacial shear. The equation for local heat transfer coefficient that they presented was:

$$\frac{h_c(z) \mu_l}{k_l \rho_l^{1/2}} = 0.045 (Pr_l)^{1/2} \tau_w^{1/2} \quad (2.13)$$

where  $\tau_w$  is the wall shear stress. In calculating the wall shear stress account must be taken of the interfacial shear and the gravitational momentum of the condensing vapor and the effect of the vapor mass transfer on the interfacial shear stress must be included. However in the analysis by Carpenter and Colburn (7), the gravitational and momentum terms were neglected and the wall shear stress was equated to the interfacial shear stress in evaluating an average heat transfer coefficient:

$$\frac{\bar{h}_c \mu_l}{k_l \rho_l^{1/2}} = 0.065 (Pr_l)^{1/2} \tau_i^{1/2} \quad (2.14)$$

where

$$\tau_i = f_i \frac{\overline{W}_v^2}{2\rho_v} \quad (2.15)$$

$$\text{and } \overline{W}_v = \left[ \frac{W_{v, in}^2 + W_{v, in} W_{v, out} + W_{v, out}^2}{3} \right]^{\frac{1}{2}} \quad (2.16)$$

Soliman, Schuster and Berenson (14) improved the Carpenter and Colburn analysis and suggested a better equation for local heat transfer coefficient with the help of further experimental data (Figure 10).

$$\frac{h_c(z)}{k_l} \frac{\mu_l}{\rho_l^{1/2}} = 0.036 (\text{Pr}_l)^{0.65} F_o^{\frac{1}{2}} \quad (2.17)$$

where  $F_o$ , the wall shear stress, is affected by three factors; gravity  $F_a$ , momentum  $F_m$ , and friction  $F_f$ .

$$F_o = F_a + F_m + F_f \quad (2.18)$$

$F_f$ , the frictional shear stress exists at the vapor liquid interface and acts in a direction opposite to flow.

$$F_f = f_v \frac{S_v}{S} \left( 1 + \frac{A_l}{A_v} \right) \quad (2.19)$$

$$\text{where } f_v = \frac{g_c A_v}{S_v} \left( \frac{\Delta P}{\Delta z} \right) \text{ TPF} \quad (2.20)$$

$$F_m = \frac{DG^2}{4\rho_v} \left( \frac{\Delta x}{\Delta z} \right) \left[ a_1 \left( \frac{\rho_v}{\rho_l} \right)^{1/3} + a_2 \left( \frac{\rho_v}{\rho_l} \right)^{2/3} + \dots + a_5 \left( \frac{\rho_v}{\rho_l} \right)^{5/3} \right] \quad (2.21)$$

The void fraction correlation due to Zivi (15) is used in the derivation of this equation. The coefficients  $a_1, a_2, \dots, a_5$  are:

$$a_1 = 2x - 1 - \beta x$$

$$a_2 = 2(1 - x) \beta$$

$$a_3 = 2(1 - x - \beta + \beta x)$$

$$a_4 = \frac{1}{x} - 3 + 2x$$

$$a_5 = \beta \left( 2 - \frac{1}{x} - x \right)$$

Figure 10. Local Heat Transfer Data for Condensation Inside Tube (Line represents Equation 2.14). (14)

$x$  is the quality and  $\beta$  is the ratio of mean liquid film velocity to the interfacial velocity.

$$V_{\ell_i} = \beta V_{\ell} \quad (2.22)$$

where  $V_{\ell}$  (average liquid velocity) is:

$$V_{\ell} = \frac{(1-x) W_t}{\rho_{\ell} (1-\alpha) A} \quad (2.23)$$

and  $\alpha$ , the void fraction as proposed by Zivi is:

$$\alpha = \frac{1}{1 + \left( \frac{1-x}{x} \right) \left( \frac{\rho_v}{\rho_{\ell}} \right)^{2/3}} \quad (2.24)$$

The effect of the gravitational field on the shear stress  $F_a$  is given by:

$$F_a = \frac{D}{4} (1-\alpha) (\rho_{\ell} - \rho_v) g \sin \theta \quad (2.25)$$

Soliman, et al., analysis also presents a means of predicting the onset of liquid runback in the presence of an adverse gravitational field.

Equations 2.17 through 2.25 are also valid for the case of upward vapor flow. In the force balance, the gravity term will, however, be negative.

$$F_o = F_f + F_m - F_a \quad (2.26)$$

The gravity contribution  $F_a$ , although quite negligible at high quality for vertical downflow, is very significant for the case of upward flow.

→ In fact, to avoid flooding of tubes, the gravity term should dominate.

As pointed out earlier, to avoid plugging and slugging of tubes in a reflux condenser, the vapor velocity must be below a critical value. English, et al., (2) conducted an experimental study to determine the effect of various factors on the flooding point. A plot of

pressure drop versus the vapor mass flow rate defines the flooding point adequately (Figure 11).

As the gas rate increases, pressure drop increases slowly and when the loading begins, there is a sharp rise and then the second break point in Figure (11) denotes the flooding point.

Based on 56 flooding determinations, English et al. (2) gave the following equation for flooding velocity:

$$G = 1550 D^{0.3} \rho_{\ell}^{0.46} \sigma^{0.9} \left( \rho_v^{0.5} / \mu_{\ell}^{0.14} \right) (\cos \theta)^{.32} \left( \frac{L}{G} \right)^{0.07} \quad (2.27)$$

where G - Maximum allowable vapor mass velocity, lb/hr sq ft.

D - Inside diameter of tube, inches

$\rho_{\ell}, \rho_v$  - Liquid and vapor density respectively, lb/cu ft

$\mu_{\ell}$  - Liquid viscosity, centipoise

$\alpha$  - Surface tension, dynes/cm

$\theta$  - Tube taper angle, degrees

Equation (2.26) is shown graphically in Figure 12. All factors such as gas and liquid rates, physical properties, tube diameter and the angle of taper on the tube inlet were taken into account experimentally.

Later, Diehl and Koppany (16) developed a correlation to predict the vapor flooding velocity for vapor-liquid counterflow in vertical tubes. A broad range of physical properties and tube sizes was covered in their experiments and the correlation was tested for a wide range of operating conditions including the English et al. data. The correlation is:

$$V_f = F_1 F_2 \left( \frac{\sigma}{\rho_v} \right)^{0.5} \quad \text{for} \quad F_1 F_2 \left( \frac{\sigma}{\rho_v} \right)^{0.5} > 10 \quad (2.28)$$

Figure 11. Pressure Drop versus Gas Mass Velocity  
(n-Propyl Alcohol with 75° Diagonally-cut Tube End).

Figure 12. Flooding Correlation Based on 56 Flooding Determinations. (1)

$$V_f = 0.71 \left[ F_1 F_2 \left( \frac{\sigma}{\rho_v} \right)^{0.5} \right]^{1.15} \quad \text{for } F_1 F_2 \left( \frac{\sigma}{\rho_v} \right)^{0.5} < 10 \quad (2.29)$$

where;

$$F_1 = \left[ d_i / \left( \frac{\sigma}{80} \right) \right]^{0.4} \quad (2.30)$$

$$F_1 = 1.0 \quad \text{if } d_i / \left( \frac{\sigma}{80} \right) \geq 1.0 \quad (2.31)$$

$$F_2 = \left( \frac{L}{G} \right)^{0.25} \quad (2.32)$$

Since the equations are dimensional, the units to be used are:

$$\begin{array}{ll} \sigma - \text{dynes/cm} & \rho_v, \rho_l - \text{lbm/ft}^3 \\ d_i - \text{inches} & L, G - \text{lbm/hr ft}^2 \end{array}$$

and  $V_f$  is in ft/sec.

The above equations can be represented by a graph (Figure 13).

The case of binary and multicomponent vapor condensation in a knockback condenser has not yet been fully explored. This is because of complications due to mass transport in addition to flooding possibilities. The basic equations for handling binary mixtures were first formulated by Colburn and Drew (17) and have recently been programmed by Price and Bell (18).

For multicomponent vapor condensation, a rigorous analysis is still under development. Only an approximate design procedure is available. It was first proposed by Silver (19) and later modified by Ward (20). Ward's analysis, however, neglects sensible heat of cooling the condensate and the transport of this heat through the condensate film. Bell and Ghaly (3) modified Ward's analysis to account for the above shortcoming.

Figure 13. Flooding Velocity Correlation for Gas-Liquid Countercurrent Flow in Vertical Tubes. (16)

The main assumption made in this type of analysis is that the mass transfer resistance in the vapor phase can be replaced by a conservative estimate of the heat transfer resistance in the vapor. The present analysis assumes the validity of this approach for a knockback condenser.

The condensate heat transfer coefficient is estimated by the modified Carpenter and Colburn equations as suggested by Soliman et al. (14). Due to vapor shear the condensate layer becomes turbulent at much lower values of Reynolds number than in the absence of vapor shear. The transition Reynolds number was found to be equal to 240 (7). At lower Reynolds number, the condensate heat transfer coefficient is estimated by both Nusselt's equation and Colburn's equation. The higher value is chosen for design purposes. In the presence of vapor shear, Soliman et al. found by experiments the value of  $b_1 = 0.036$  where

$$b_1 \text{Pr}_\ell^C = \frac{h_c(z) \mu_\ell}{k_\ell \rho_\ell^{1/2} F_o^{1/2}} \quad (2.33)$$

and  $C = 0.65$

In the equation presented by Carpenter and Colburn (7),  $b_1$  was equal to 0.045 and  $C$  equal to  $F$ . Carpenter and Colburn assumed that the interfacial shear stress was equal to wall shear stress and hence the difference in the values of  $b_1$  and  $C$ .

## CHAPTER III

### FILM FLOW MODEL AND HEAT TRANSFER MODEL

#### Pure Component Condensation

The basic design equation used here are those developed by Soliman et al. (14). The stress acting downwards is taken as positive. Since in the case of upward vapor flow, gravity opposes the vapor shear at the vapor-liquid interface, the friction term is negative.

As mentioned earlier, the main concern in reflux condensers is that flooding be avoided, i.e., the sum of the three terms (friction, gravity and momentum) should not be equal to zero, i.e.,

$$F_o = F_a + F_m - F_f > 0 \quad (3.1)$$

For a fixed tube diameter, the flooding velocity depends on the vapor density and liquid surface tension (]6). In very small diameter tubes, countercurrent flow is not possible due to surface tension effects.

Diehl and Koppany (]6) found that there is a definite critical diameter, above which the flooding velocity is no longer dependent on the choice of the diameter. This critical diameter is dimensional;

$$D_c = \frac{\sigma}{80} \quad (3.2)$$

where  $\sigma$  is in dynes/cm and  $D_c$  is in inches.

The final form of the flooding correlation is the set of equations 2.28 through 2.32. The recommended operating velocity is about 70 percent

of the flooding vapor velocity. The main assumptions governing the analysis of Soliman et al. are:

- a. Annular flow is assumed throughout the condensing length (Figure 14).
- b. In the presence of vapor shear, transition from laminar to turbulent flow occurs at a Reynolds number,  $\frac{4W_\ell}{\pi D \mu_\ell}$ , of about 250.
- c. There is zero slip at the vapor-liquid interface.
- d. Carpenter-Colburn type heat transfer coefficient (with vapor shear effect) is applicable in turbulent flow regime and Nusselt equation in laminar flow regime.

The details of development of the various terms in equation 3.1 are given by Soliman et al. (14). The final form of the equations are:

#### Gravity term

$$\left( \frac{F_a}{\frac{8W_T^2}{\pi^2 \rho_v D^4}} \right) = 0.5 F_{rt}^{-1} \left[ 1 - \left\{ 1 + \frac{(1-x)}{x} \left( \frac{\rho_v}{\rho_\ell} \right)^{2/3} \right\}^{-1} \right] \quad (3.5)$$

$$\text{where } F_{rt} = \frac{16 W_T^2}{\pi^2 D^5 g(\rho_\ell - \rho_v) \rho_v} \quad (3.4)$$

#### Friction term

$$\frac{F_f}{\frac{8W_T^2}{\pi^2 \rho_v D^4}} = 0.045 Re_T^{-0.2} \left[ x^{1.8} + 5.7 \left( \frac{\mu_\ell}{\mu_v} \right)^{0.0523} (1-x)^{0.47} \right. \\ \left. x^{1.33} \left( \frac{\rho_v}{\rho_\ell} \right)^{0.261} + 8.11 \left( \frac{\mu_\ell}{\mu_v} \right)^{0.105} (1-x)^{0.94} \right. \\ \left. x^{0.86} \left( \frac{\rho_v}{\rho_\ell} \right)^{0.522} \right] \quad (3.5)$$

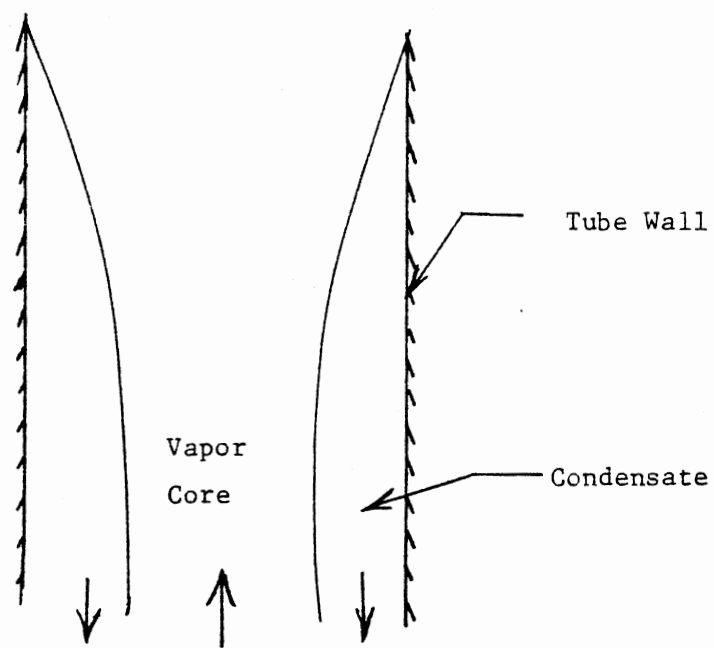

Figure ■ Annular Film Flow.

$$\text{where } Re_T = \frac{4W_T}{\pi D u_v} \quad (3.6)$$

and finally,

$$\begin{aligned} \left( \frac{F_m}{\frac{8W_T^2}{\pi^2 \rho_v D^4}} \right) = 0.5 \left( D \frac{\Delta x}{\Delta z} \right) & \left[ 2(1-x) \left( \frac{\rho_v}{\rho_l} \right)^{2/3} + \left( \frac{1}{x} - 3 + 2x \right) \left( \frac{\rho_v}{\rho_l} \right)^{4/3} \right. \\ & + (2x - 1 - \beta x) \left( \frac{\rho_v}{\rho_l} \right)^{1/3} + \left( 2\beta - \frac{\beta}{x} - \beta x \right) \left( \frac{\rho_v}{\rho_l} \right)^{5/3} \\ & \left. + 2(1 - x - \beta + \beta x) \left( \frac{\rho_v}{\rho_l} \right) \right] \quad (3.7) \end{aligned}$$

where  $\beta$  is the ratio of the interfacial velocity to the average liquid layer velocity. In the present case, the sum of the above three effects gives the shear stress at the tube wall.

$$F_o = F_a + F_m - F_f$$

It should be noted that the left-hand sides of equations 3.3, 3.5 and 3.7 are dimensionless and they will be denoted as  $F_a'$ ,  $F_f'$  and  $F_m'$ .

#### Evaluation of Local Heat Transfer Coefficient

On the basis of experimental results, Carpenter and Colburn (17) arrived at the following equation for local condensate heat transfer coefficient:

$$\frac{h_c(z) u_l}{k_l \rho_l^{1/2}} = 0.043 (Pr_l)^{1/2} F_o^{1/2} \quad (3.8)$$

However, Soliman et al. (14) found the coefficient of 0.043 and the Prandtl number of exponent of 0.5 unsatisfactory over a wide range of Prandtl numbers. Based on their experiments, Soliman et al. (14)

found that a coefficient of 0.036 and an exponent 0.65 more satisfactory. The modified equation is then:

$$\frac{h_c(\bar{z}) \mu_\ell}{k_\ell \rho_\ell^{1/2}} = 0.036 \text{Pr}_\ell^{0.65} F_o^{1/2} \quad (3.9)$$

Figures 10 and 15 show how from the data these two constants are determined.

### Mass and Energy Balance for Pure Component Condensation

In the present analysis, only a saturated vapor feed has been considered; i.e.,

$$Q_T = W_T \lambda$$

This however, can be modified if required to handle superheated vapor. An additional heat balance to desuperheat the feed will be required. All calculations are carried out for a single tube. If the total heat duty is specified, then the total number of tubes required may be obtained by dividing the total heat duty by the heat transferred per tube.

First the flooding velocity of the vapor is computed by the Diehl and Koppany correlation. Then the inlet velocity is taken as 70 percent of the flooding velocity (Figure 16). If only a fraction of the vapor is condensed then;

$$W_{v, \text{ out}} = W_{v, \text{ in}} (\text{FC})$$

where FC is the fraction condensed.

$$Q_T/\text{tube} = W_v \lambda \quad (3.10)$$

$$W_{\text{cool}}/\text{tube} = \frac{Q_T/\text{tube}}{C_{p, \text{cool}}(T_2 - T_1)} \quad (3.11)$$

Figure 15. Evaluation of Prandtl Number Exponent in Equation 2.14. (14)

Figure 16. Mass Balance for Pure Component Condensation.

where  $T_1$  and  $T_2$  are the inlet and outlet coolant temperatures respectively. The computational procedure for pure component condensation is as follows:

1. Assume length of tube ( $L_T$ )
2. Startup at  $z = 0$ , calculate  $h_c(z)$ ,  $i$ , and  $U'_{i,i}$  where  $U'_{i,i}$  is the overall heat transfer coefficient

$$U'_{i,i} = \frac{1}{\frac{1}{h_c(z)} + R_{fi} + \frac{\Delta x_w}{k_w} \left(\frac{D}{OD}\right) + R_{fo} \frac{D}{OD} + \frac{1}{h_{cool}} \frac{D}{OD}} \quad (3.12)$$

where  $R_{fi}$ ,  $R_{fo}$  are the inside and outside fouling factors, respectively, and

$\Delta x_w$  wall thickness

OD outer diameter of tube

3. Choose a very small increment  $\Delta z$ . Assuming that the values computed at  $i$  hold good over the increment  $\Delta z$ ,

$$T_{w,i+1} = \frac{T_{sat} - U'_{i,i} (T_{sat} - T_{i,i})}{h_c(z)} \quad (3.13)$$

The incremental heat recovery is

$$\Delta Q_{i+1} = \pi D \Delta z U'_{i,i} (T_{sat} - T_i) \quad (3.14)$$

The amount of vapor condensed is given by

$$W_{c,i+1} = \Delta Q_{i+1} / \lambda \quad (3.16)$$

The mass flow rates of vapor and liquid are:

$$W_{v,i+1} = W_{v,i} - W_{c,i+1} \quad \text{and} \quad (3.16a)$$

$$W_{l,i+1} = W_{l,i} + W_{c,i+1} \quad (3.16b)$$

The total mass flow rate at  $(i + 1)$  iteration is

$$W_{l, i + 1} + W_{v, i + 1} \quad (3.16c)$$

and quality

$$X_{i + 1} = W_{v, i + 1} / W_{T, i + 1} \quad (3.17)$$

4. Calculate  $h_c(z)_{, i + 1}$  and  $V_{i, i + 1}$

5. The coolant temperature is

$$T_{i + 1} = T_i \pm \Delta Q_{i + 1} / C_{p, \text{cool}} W_{\text{cool}} \quad (3.18)$$

where the positive sign should be used if the coolant and the vapor are cocurrent and the negative sign if the coolant and the vapor are in counter current flow (Figure 17b)

Check if  $\text{ABS} \left| Q_T - Q_{i + 1} \right| \leq \epsilon$

where  $\epsilon$  is a very small number and then check if  $(\Sigma z - L_T) \leq \epsilon$

No, go on to step 3.

Yes, the length of the tube has converged.

### Multicomponent Condensation

As mentioned earlier, no rigorous method is available at present to handle multicomponent condensation. This is because of the mass transport involved. The approximate design procedure as presented by Bell and Ghaly (3) will be used in the analysis.

The basic assumptions in this method are:

1. The liquid and vapor composition are in equilibrium at the vapor bulk temperature.

2. Liquid and vapor enthalpies are those of the equilibrium phases at the vapor bulk temperature.

a) Cocurrent Flow

b) Countercurrent Flow

Figure 17. Flow Configuration for Vapor and Coolant

3. The sensible heat of the vapor is transferred from the bulk vapor to the vapor liquid interface by a convective heat transfer process. The heat transfer coefficient is calculated from a correlation for the geometry involved, assuming that only the vapor phase is present and using vapor physical properties and total vapor flow rate.

4. Total latent heat of condensation and sensible heat of the cooling condensate are transferred through the entire thickness of the liquid Film.

Figure 18 shows typical multicomponent condensation profiles for a system consisting of two condensable components and one non-condensable. Figure 19 shows the idealized model for a multicomponent condensation.

By heat balance,

$$\frac{dQ_{sv}}{dA_i} = h_{sv} (T_v - T_i) \quad (3.19)$$

$$\frac{dQ_T}{dA_i} = U_i' (T_i - T_{cool}) \quad (3.20)$$

Eliminating  $T_i$  between equations results in a form that can be readily used in the design.

$$\frac{dQ_T}{dA} = \frac{U_i' (T_v - T_{cool})}{1 + \frac{ZU_i'}{h_{sv}}} \quad (3.21)$$

where

$$Z = \frac{dQ_{sv}}{dQ_T} \quad (3.22)$$

✓ Figure 18. Multicomponent Condensation Profile. (18)

Figure 19. Idealized Model for Multicomponent Condensation. (3)

The single phase vapor sensible heat transfer coefficients  $h_{sv}$ , was calculated using the Seider-Tate equation

$$h_{sv} = 0.23 \left( \frac{k_v}{D} \right) \left( \frac{C_p \mu}{k} \right)_v^{0.33} \left( \frac{D W_v}{\left( \frac{\pi}{4} D \right)^2 u_v} \right)^{0.8} \left( \frac{\mu}{\mu_s} \right)_v^{0.14} \quad (3.23)$$

where  $W_v$  varies for every finite increment.

### Mass and Energy Balance for Multicomponent Condensation

As in the case of pure component condensation, the flooding vapor velocity is first estimated using the Diehl and Koppany correlations. The operating vapor flow rate is then calculated as:

$$W_v = 0.7 V_f \left( \frac{\pi D}{4.0} \right)^2 \rho_v \quad (3.24)$$

The average value of the vapor mixture density can be used if the properties do not vary much over the range of temperatures.

Since the inlet vapor mixture flow rate, temperature, pressure and composition of the vapor mixture will generally be specified, it is possible to calculate the intermediate liquid and vapor flow rates and the compositions by equilibrium calculations. If the fraction condensed is specified, the outlet temperature can be obtained or vice versa.

In the present analysis, all these parameters were obtained by using the GPA\*SIM program (4).

Here, at a given temperature and pressure, a value of L/F is assumed and the  $k_i$  values for each component are taken at the pressure and temperature specified.

If  $\frac{L}{F}$  assumed is the same as  $\frac{L}{F}$  calculated

$$\left( \text{Actually Abs } \frac{L}{F} \text{ assumed} - \frac{L}{F} \text{ calculated} \right) \leq 0.0005$$

then the composition at the required temperature and pressure is obtained.

### Calculation of $\frac{L}{F}$

1. Assume  $\frac{L}{F}$

$$2. \quad \phi\left(\frac{L}{F}\right) = \frac{\sum M_i (1 - k_i)}{\frac{L}{F} (1 - k_i) + k_i} \quad (3.25)$$

$$3. \quad \phi' \left(\frac{L}{F}\right) = \frac{-\sum M_i (1 - k_i)^2}{\frac{L}{F} (1 - k_i) + k_i} \quad (3.26)$$

$$4. \quad \left(\frac{L}{F}\right)_{\text{new}} = \left(\frac{L}{F}\right)_{\text{old}} - \frac{\phi(L/F)}{\phi'(L/F)} \quad (3.27)$$

$$5. \quad \text{If ABS } \left| \left(\frac{L}{F}\right)_{\text{new}} - \left(\frac{L}{F}\right)_{\text{old}} \right| \leq 0.0005 \quad (3.28)$$

Yes - Go to 6

No - Go to 1

$$6. \quad x_i = \frac{M_i}{\frac{L}{F}(1 - k_i) + k_i} ; y_i = k_i x_i$$

Similar calculations can be done for the condensing range of the vapor to the condenser, choosing small increments of  $\Delta T$ .

Since the ratio of vapor to liquid is known at various points in the condenser as a function of  $Q$  the liquid and the vapor flow rates can be readily calculated (Figure 20).

Figure 20. Mass and Energy Balance for Multicomponent Condensation.

In order to calculate the heat recovered in each increment

$$\frac{dQ_T}{dA_i} = \frac{U'_{i,i} (T_{v,i} - T_{cool,i})}{1 + \frac{Z_i U'_{i,i}}{h_{sv,i}}} \quad (3.29)$$

where  $T_{v,i}$  is the bulk vapor temperature

$$\text{and } \frac{dQ_T}{dA_i} = \frac{dQ_{sv} + dQ_{sl} + dQ_l}{dA_i} \quad (3.30)$$

GPA\*SIM (4) program was used to obtain the enthalpy of vapor and total enthalpy at each increment. The stepwise calculation procedure is as follows:

1. Using GPA\*SIM program, precalculate the condensation curve, i.e., the vapor, liquid and total flow rates at various increments of  $\Delta T$ .

2. Assume length of tube ( $L_T$ )

3. At  $z = 0$ , calculate  $h_c(z)$ ,  $U'_{i,i}$  and  $h_{sv,i}$

$$\text{Set } \Delta Q_{sv,i} = 0$$

$$\Delta Q_{T,i} = 0$$

$$h_{sav,i} = 0$$

$$Z_i = 0$$

$$Q_{y,i} = 0$$

where  $Q_{y,i}$  is the total heat recovered up to increment in question starting from  $z = 0$ .

4. Increment  $z_{i+1} = \Delta z$  (over which the bulk vapor temperature goes from  $T_{v,i}$  to  $T_{v,i+1}$ )

5. Calculate the differential vapor sensible load as

$$\Delta Q_{sv,i+1} = \left[ (W_{v,i+1} + W_{v,i}) / 2.0 \right. \\ \left. (h_{v,i} - h_{v,i+1}) \right] \quad (3.31)$$

where  $h_v$  is the vapor enthalpy.

$$6. \quad Q_{y, i+1} = W_{v, \text{inlet}} (h_{T, i+1} - h_{T, i}) \quad (3.32)$$

and the differential heat recovered is

$$\Delta Q_{T, i+1} = Q_{y, i+1} - Q_{y, i} \quad (3.33)$$

7. The coolant temperature is

$$T_{i+1} = T_c \pm \Delta Q_{T, i+1} / C_{p, \text{cool}} W_{\text{cool}} \quad (3.34)$$

$$8. \quad Z_{i+1} = \Delta Q_{sv, i+1} / \Delta Q_{T, i+1} \quad (3.35)$$

$$9. \quad H_{svav, i+1} = (h_{sv, i+1} + h_{sv, i}) / 2.0 \quad (3.36)$$

10. Calculate the condensation heat transfer coefficient,

$$h_c(z), \quad i+1, \quad \text{and} \quad U'_{i, i+1}$$

$$11. \quad \text{Factor}_{i+1} = \frac{1 + Z_{i+1} \frac{U'_{i+1}}{h_{svav, i+1}}}{U'_{i, i+1} (T_{v, i+1} - T_{i+1})} \quad (3.37)$$

12. Calculated increment is

$$\Delta z_{\text{cal}} = \frac{(\text{Factor}_{i+1}) \Delta Q_{T, i+1}}{\pi D} \quad (3.38)$$

check if  $\text{Abs}|\Delta z, \text{assumed} - \Delta z, \text{cal}| \leq \epsilon$

Yes, repeat for the next  $\Delta T$  increment and go to step 4.

No, choose another  $\Delta z$  and go to step 10.

13. At the end of all  $\Delta T$  increments, check if  $(\Sigma \Delta z - L_T) \leq \epsilon$ .

Yes, length of the tube has converged.

No, assume a new  $L_T$  and go to step 2.

The length of the tubes then  $\Sigma \Delta z$ . Alternatively, a plot of

$$\frac{1 + z \frac{U'_i}{h_{sv}}}{U'_i (T_v - T_{\text{cool}})} \quad \text{versus} \quad Q_T$$

can be drawn and the area under the curve will give the area of the tube ( $\pi DL_T$ ) from which the length can be computed. In this case also, calculations were done for a single tube. The number of tubes required can be calculated

$$N_{\text{Tubes}} = \frac{\text{Total mass flow rate}}{\text{Mass flow rate per tube}} \quad (3.39)$$

The details of the shell-side design are not present in this analysis. As mentioned earlier, the coolant side coefficient was assumed in the example calculations.

## CHAPTER IV

### RESULTS AND DISCUSSION

A computer program has been written to handle pure component as well as multicomponent condensation. The program computes the flooding velocity in the reflux condenser. Then, based on the maximum allowable design vapor inlet velocity, point values of the condensate heat transfer coefficients, overall heat transfer coefficients and heat load are calculated. The length of tube is determined by trial and error procedure. For a given total heat load, the number of tubes required is evaluated.

Since the operating vapor velocity was taken to be below the flooding velocity (70 percent flooding velocity) of the vapor, a downward flow of the condensate is ensured. This can be seen in Figures 21 and 24. The gravity term should dominate to prevent flooding in the tubes. If the inlet velocity of the vapor is high enough to cause flooding in the tubes, the condensate will cease to flow down the tube walls. Once the sum of the three effects (momentum, gravity and friction) equals zero, the liquid will slowly start to flow upwards and the flow becomes highly unstable. If the velocity is maintained above flooding, there will be a point when the condensate will be carried out of the tube. Hence, the inlet vapor rate into a reflux condenser is the critical design parameter.

As can be seen from the results of examples in Appendix A, the flooding velocity is surprising very low even for a 1.334 in. inside tube diameter.

For the pure component, the flooding velocity is 6.2 ft/sec and for the multicomponent case, it is about 2.5 ft/sec. However, due to higher vapor density for the latter case, the mass flow rate is higher per tube.

The shortcomings of the model are:

1. The use of modified Carpenter and Colburn equations as presented by Soliman et al. (1) for condensate heat transfer coefficient, including vapor shear effects.

$$h_c(z) = 0.036 \text{ Pr}_l^{0.65} \text{ Fo}^{0.5} \left( \frac{k\rho}{\mu} \right)_l^{0.5}$$

This equation was obtained as a result of experiments, strictly based on data collected for vertical downward flow of vapor. Hence its accuracy for an upward vapor flow is not known and requires experimental verification.

2. The algorithm for the multicomponent case is only an approximate design method because of the assumptions made. The heat transfer resistance in the vapor is overestimated, neglecting the mass transfer resistance. Until a rigorous method is developed to handle multicomponent mixtures and experimental data are made available for reflux condensers, one cannot comment upon the accuracy of the results obtained. However, the coefficients and length of the tubes look reasonable. For safe operation of the condenser, the area provided should be about 20-25 percent in excess of the area computed.

The momentum term as derived by Soliman et al. goes to zero in the case of total condensation for countercurrent flow. Although the changes in momentum may be negligible (as can be seen from Tables VI and XV in Appendix A) the term should not go to zero. This will however, not alter the results significantly.

## CHAPTER V

### CONCLUSIONS AND RECOMMENDATIONS

This thesis deals with an approximate design procedure for pure component and multicomponent reflux condensers.

The basic mechanism of reflux condensation in a vertical tube is still not fully known. This is due to the flooding possibilities.

A computer program is presented in Appendix C that will give the design parameters, such as flooding velocity, heat recovered per tube, the heat transfer coefficients and the length of the tube for a reflux operation. The result can be obtained in SI units or U. S. customary units.

The program however could be modified to accommodate the prediction of various physical properties, which in this program are read as input data. Also, for multicomponent condensation, the preliminary calculations, such as condensing path and enthalpy predictions are not included in the program. These were done by using GPA\*SIM (4) but could be included as a callable routine. Also, the program handles saturated vapors alone. It could be modified to handle superheated vapors as well as vapor mixtures containing non-condensables.

The results have been presented at every increment using point condition equations. In order to avoid unrealistic heat transfer coefficients, the higher of the two (Nusselt and Carpenter-Colburn) was chosen. This applies especially near the top of the tubes where

the Nusselt region can be expected, due to decreasing vapor velocity.

The main point of concern is the lack of experimental data to compare the accuracy of the result obtained. Further research is greatly desired to study the effect of high vapor velocities on fluid flow, especially in determining the actual mechanism of the flooding phenomena.

APPENDIX A

SAMPLE CALCULATIONS

Pure Component Condensation

It is desired to condense saturated methanol vapor at about 60 psig (235 F). Water is available at 85 F and it leaves at 120 F. The inside and outside fouling are assume to be 0.0005 and 0.001 hr ft<sup>2</sup> F/BTU respectively. The coolant heat transfer coefficient is assumed to be 1000 BTU/hr ft<sup>2</sup> F.

Estimate the flooding velocity, the heat recovered per tube, the length of the tube and the number of tubes required to recover  $2.5 \times 10^6$  BTU/hr. Tubes with outer diameter of 1.5 inches and 14 BWG are to be used.

The following results were obtained from the computer program. The length of the tube was obtained by iterating from the bottom of the tube (length = 0), until the assumed length was equal to the calculated length. The results are given for every increment.

TABLE I  
INPUT DATA

---

Saturation Temperature	235.0	Deg.F
Pressure	60.0	Psig.
Coolant Specific Heat	1.0	BTU/lbm Deg.F
Latent Heat of Condensation	440.0	BTU/lbm.
Liquid Density	46.0	Lbm/cu.ft.
Vapor Density	0.32	Lbm/cu.ft.
Vapor Viscosity	0.032	Lbm/ft hr.
Liquid Viscosity	0.39	Lbm/ft hr.
Surface Tension	13.0	Dynes/cm.
Inlet Coolant Temp.	120.0	Deg.F
Outlet Coolant Temp.	85.0	Deg.F
Liquid Thermal Conductivity	0.11	BTU/hr ft Deg.F
Wall Thermal Conductivity	26.0	BTU/hr ft Deg.F
Inside Fouling	0.0005	Hr sq.ft Deg.F/BTU
Outside Fouling	0.001	Hr sq.ft Deg.F/BTU
Liquid Specific Heat	0.5	BTU/lbm Deg.F
Coolant Heat Transfer Coeff.	1000.0	BTU/hr sq.ft Deg.F
Outside Diameter of Tube	1.5	Inches
Wall Thickness	0.083	Inches

$$\text{Dimensionless } F' = \frac{F}{\left( \frac{8W_T^2}{\pi^2 \rho_V D^4} \right)}$$

A plot of  $F'$  versus quality is shown in Figure 21. Graphical evaluation of length is shown in Figure 22. The length of the tube from numerical analysis was 2.15 feet. The number of tubes required to recover  $2.5 \times 10^7$  BTU/hr was found to be equal to 130.

Figure 21. Dimensionless Forces versus Quality

Figure 22. Graphical Evaluation of Length of Tube.

### Multicomponent Condensation

A mixture having the following composition (Table VII) is to be partially condensed from 180 F to 130 F at 150 psig in a shell and tube exchanger, arranged as a vertical reflux condenser. Cooling water enters at 85 F and leaves at 120 F. The tube diameter is 1.5 inches. The fouling rates are 0.0005 and 0.001 hr ft<sup>2</sup> F/BTU on the inside and outside respectively. The coolant coefficient is assumed to be 1000 BTU/hr ft<sup>2</sup> F.

It is required to calculate, the flooding velocity, the heat recovered per tube, length of the tube and the number of tubes required to recover  $2.5 \times 10^6$  BTU/hr.

The preliminary computation, such as the vapor-liquid equilibrium curve, densities, enthalpies were determined for various intermediate points using the GPA\*SIM (19) program. A summary of the results obtained are given in Tables VIII, IX, and X.

The physical properties are very nearly constant; hence, an average value is used throughout the entire vapor temperature range, and over the entire condensing range. These values are listed in Table VII. Surface tension, thermal conductivities and viscosities were obtained from the GPSA Engineering Data Book (20).

$$\text{Dimensionless } F' = \frac{F}{\left( \frac{8W_T^2}{\pi^2 \rho_v D^4} \right)}$$

The above is shown in Figure 25. Figure 26 is the graphical evaluation of the length of the tube. The length of the tube from numerical analysis was 11.33 feet. The number of tubes required to recover  $2.5 \times 10^7$  BTU/hr was found to be equal to 222.

Figure 2 4. Dimensionless Forces versus Quality

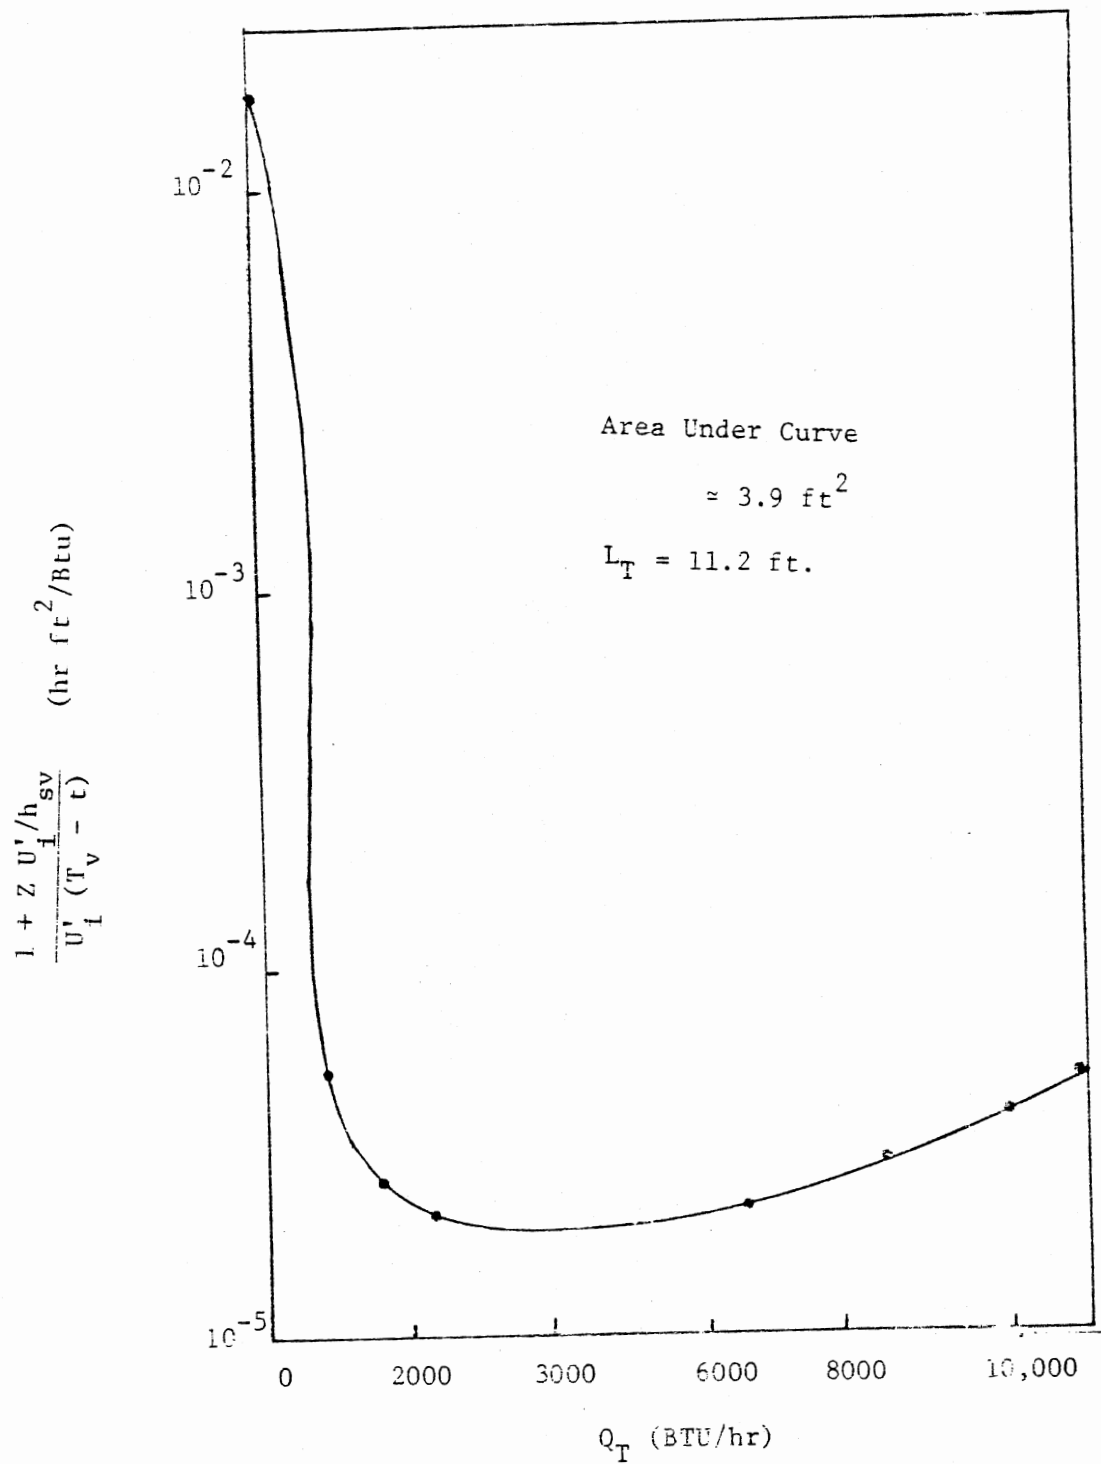

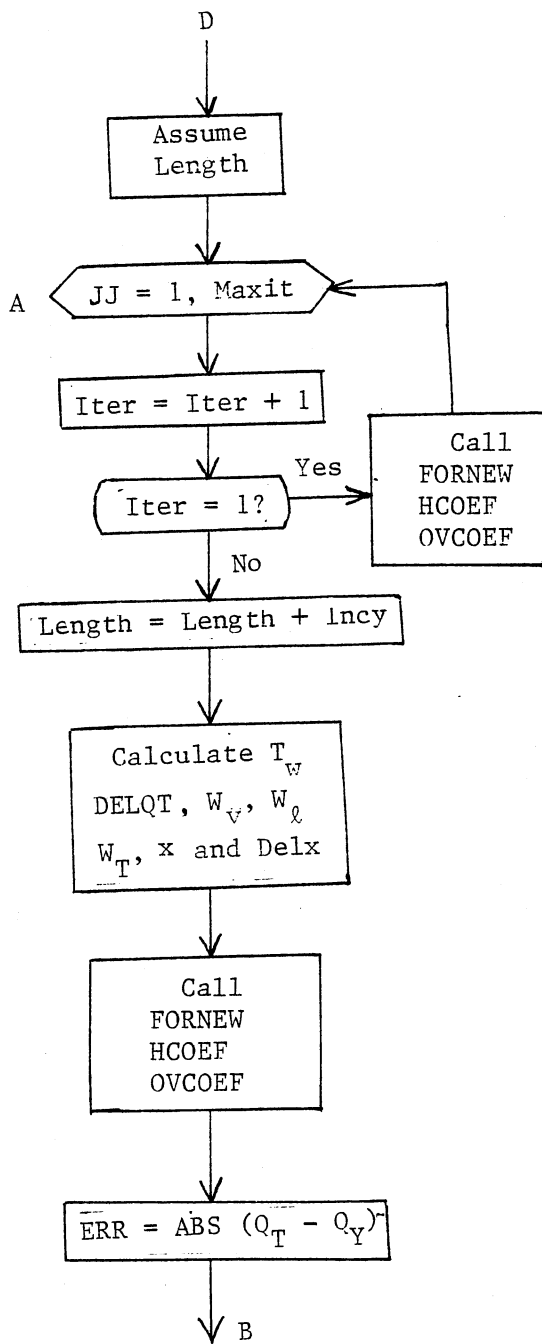

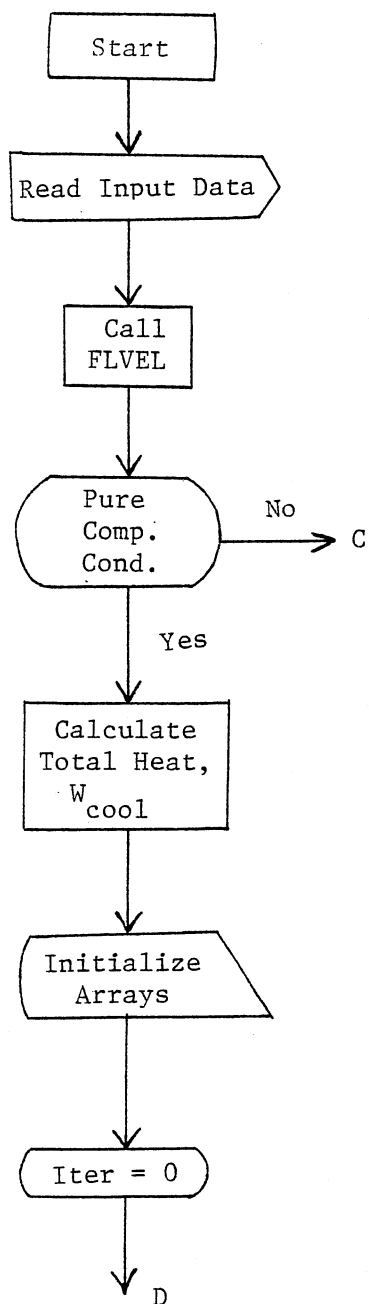

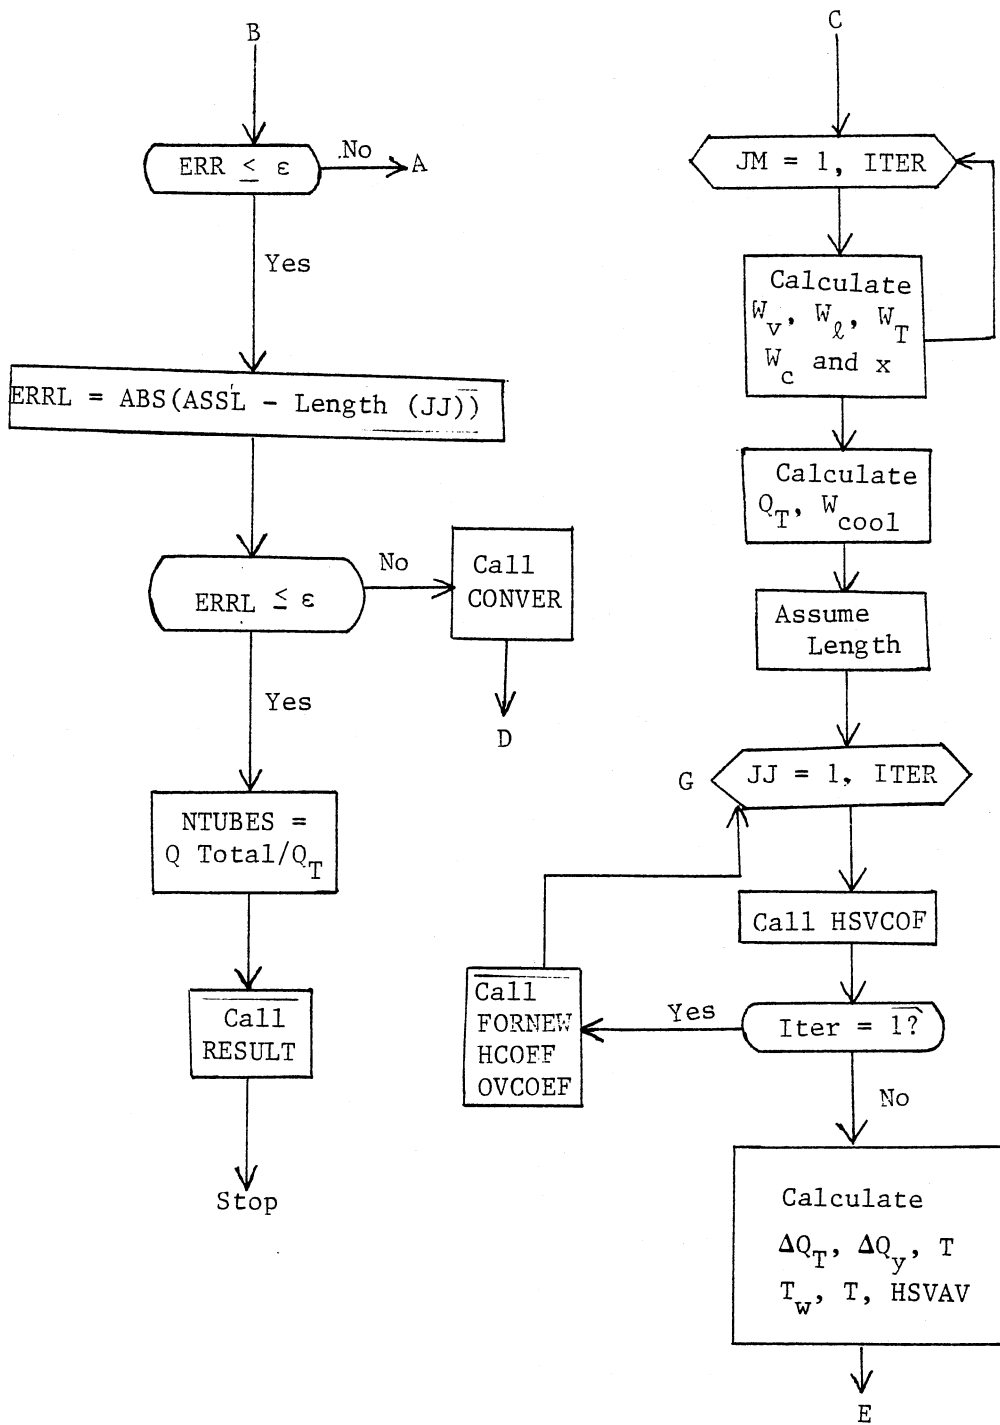

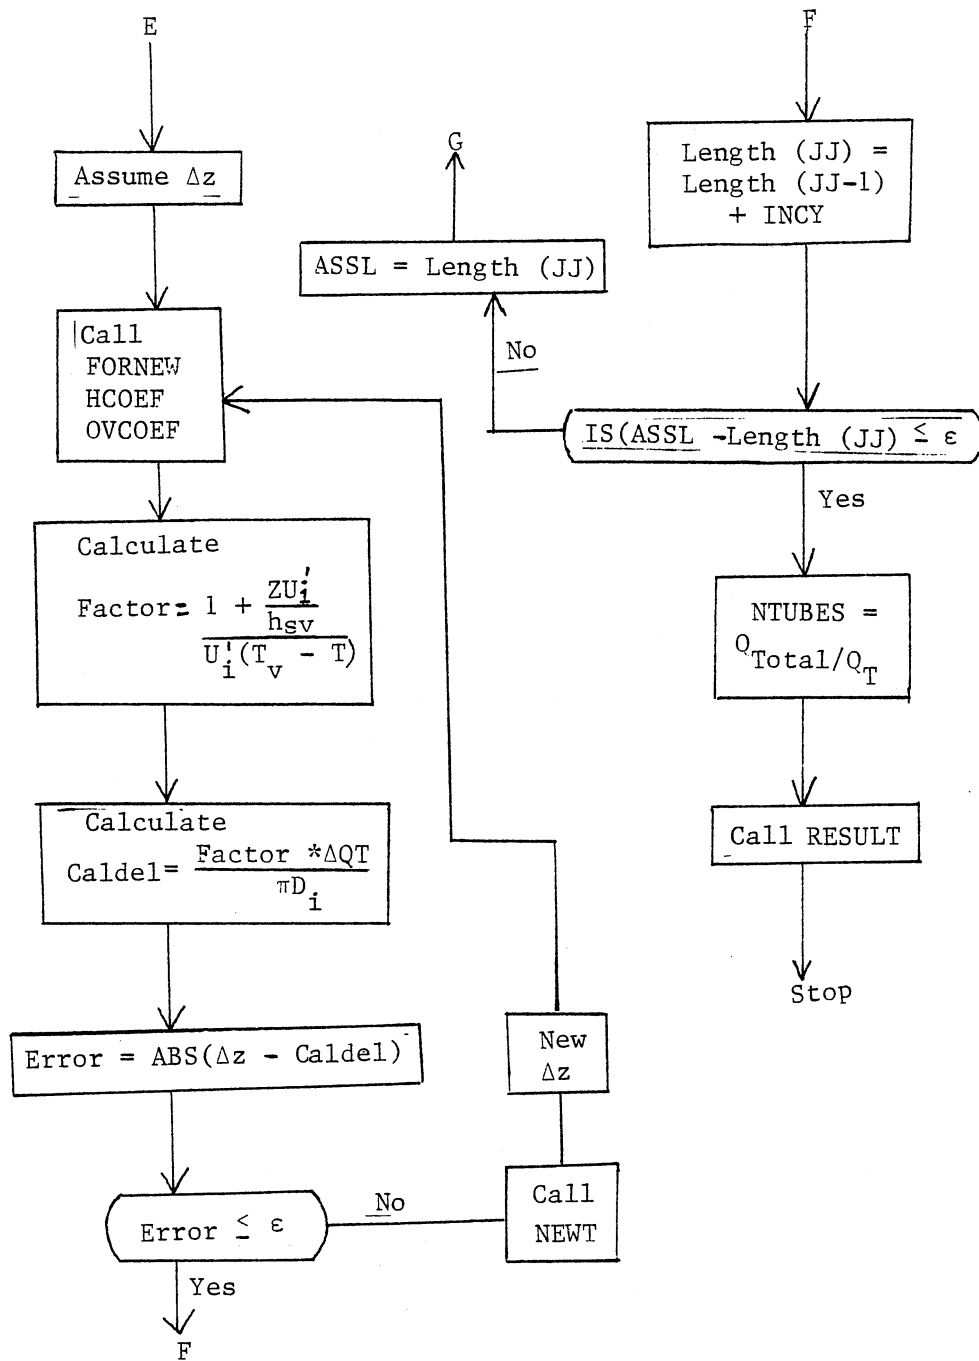

Figure 25. Graphical Evaluation of Length of the Tube.

APPENDIX B

FLOW SHEET FOR COMPUTER PROGRAM

APPENDIX C

PROGRAM DESCRIPTIONS

### SUMMARY OF PROGRAM

The main program calculates the mass flow rates of the vapor and liquid, the qualities, coolant and wall temperatures, heat recovered and the length of the tube for each  $\Delta z$  increment.

#### Subroutine Read 1

The input data consisting of the inlet conditions and the various physical properties are read in by this Subroutine.

#### Subroutine FLVEL

This Subroutine calculates the flooding velocity of the vapor using Diehl-Koppany Correlation.

#### Subroutine HCOEF

Condensation heat transfer coefficients using the modified Carpenter - Colburn equation and the Nusselt equation are computed in the Subroutine. The higher number is taken as the point value for the condensing coefficient.

#### Subroutine FORNEW

This Subroutine calculates the total shear stress ( $F_o$ ) by evaluating the three components  $F_a$ ,  $F_f$  and  $F_m$ . The equations used are those of Soliman et al.

Subroutine HSVCOF

The vapor heat transfer coefficient in the case of multicomponent condensation is calculated in this Subroutine using equation 3.

Subroutine OVCOEF

The overall heat transfer coefficient with respect to the inner area is computed.

Subroutine NEWT and Subrouting CONVER

NEWT estimates the new guess of  $\Delta z$  for the multicomponent condensation. CONVER gives the new guess of length of tube for pure component condensation. Both Subroutines use binary chop method for convergence.

Subroutine CUNIT

Converts U.S. Customary Units to SI Units.

Subroutine RESULT

Prints the calculated variables after convergence is met. All point values are printed out.

INPUT CODES FOR PROGRAMCard Set 1

Number of cards = 1

M = 0 Pure component condensation  
= 1 Multicomponent condensation

L units = 0 U.S. Customary Units  
= 1 SI units

FORMAT (2I2)

Card Set 2

Number of cards = 1

D = Inner tube diameter

OD = Outer tube diameter

PI = Value of  $\pi$

RLG = Liquid to gas ratio

SIGMA = Surface tension

HW = Coolant heat transfer coefficient

$T_1, T_2$  = Inlet and outlet coolant temperatures  
respectively

Conv = 2520.

FORMAT (9F8.0)

Card Set 3

Number of cards = 1

CPC	= Specific heat of coolant
PR	= Pressure
AKW	= Thermal conductivity of tube wall
WALLTH	= Wall thickness
RFI, RFO	= Inside and outside fouling factors of tube, respectively
G	= Gravitational constant
FORMAT	(F4.0, 5F8.0, E15.8)

Card Set 4

Number of cards = 1

AMUV, AMUL	= Viscosities of vapor and liquid, respectively
CPL	= Specific heat of liquid
AKL	= Thermal conductivity of liquid
ALAMDA	= Latent heat of condensation
RHOG, RHOL	= Densities of vapor and liquid, respectively
FORMAT	(7F10.0)

Card Set 5 (Only if M = 0)

Number of cards = 1

TSAT	= Saturation temperature of vapor at PR
INCY	= Increment in length
MAXIT	= Maximum number of iterations
FORMAT	(2F10.0, I3)

Card Set 6

Number of cards = 1

UPLT, LOWLT = Upper limit for tube length and lower  
limit for tube length

FORMAT (2F10.0)

Card Set 7 (Only if M = 0)

Number of cards = 1

COMP = Name of the pure component being  
condensed

FORMAT (3Af)

Card Set 8 (Only if M = 1)

Number of cards = 1

NCOMPS = Number of components for multicomponent  
condensation

ITER = Number of temperature increments

AVMWT = Average molecular weight

CPG = Specific heat for vapor

AKV = Thermal conductivity of vapor

FORMAT (2I3, 3F10.0)

Card Set 9 (Only if M = 1)

Number of cards = ITER

VAPTEM = Bulk vapor temperature for each increment

WTFRVA = Weight fraction of vapor for each  
increment (precalculated)

ENTHV = Vapor enthalpy

ENTHF = Total enthalpy

FORMAT (4F10.0)

Card Set 10 (Only if M = 1)

Number of cards = NCOMPS

COMPS	= Component name
AMOLFR	= Mole percent of the component at the inlet
FORMAT	(3A4, F5.0)

Card Set 11

Number of cards = 1

QTOTAL	= Total heat duty (in all tubes)
FORMAT	(E20.10)

APPENDIX D

PROGRAM LISTING

```

C
C
C PROGRAM CALCULATES THE FLOODING VELOCITY, HEAT DUTY
C RECOVERED PER TUBE AND THE LENGTH OF THE TUBE.
C IN A REFLUX CONDENSER.
C
C 'M' = 0 DENOTES PURE COMPONENT CONDENSATION
C 'M' = 1 DENOTES MULTI-COMPONENT CONDENSATION
C LUNITS=0 DENOTES OUTPUT IN BRITISH UNITS

VITA

Savithri Subramanyam

Candidate for the Degree of

Master of Science

Thesis: SIZING OF REFLUX CONDENSERS

Major Field: Chemical Engineering

Biographical:

Personal Data: Born in Coimbatore, India, May 31, 1956, the daughter of Mrs. and Mr. G. Subramanyam.

Education: Graduated from St. Frances College for Women, Secunderabad, India, in May 1975; received Bachelor of Technology degree in Chemical Engineering from Osmania University, Hyderabad, India, in April 1980; completed requirements for the Master of Science degree at Oklahoma State University in July, 1983.

Professional Experience: Teaching Assistant at the School of Chemical Engineering, Oklahoma State University, Stillwater, Oklahoma from 1980 to 1982; Computer Programmer at Water Resources Research Center, Oklahoma State University, Stillwater, Oklahoma in 1981; Research Engineering at the School of Chemical Engineering, Oklahoma State University, Stillwater, Oklahoma from 1981 to 1982.
