A SIMULATION MODEL FOR ANALYZING ALTERNATIVE
CHANGES OF THE OKLAHOMA ECONOMY AND
PROJECTING ECONOMIC VARIABLES
FROM 1967 TO 1985

Thesis Approved:

963979

## ACKNOWLEDGEMENTS

I wish to express my sincere thanks to Dr . Gerald A. Doeksen, my major adviser, for his encouragement and assistance throughout my Ph.D. program. His guidance, assistance, and suggestions in conducting this study and preparing the manuscript are deeply appreciated. Appreciation is also extended to the other members of the committee: Dr. Julian H. Bradsher, Dr. Dean F. Schreiner, and Dr. Daryll E. Ray. Special thanks are due to Dr. James S. Plaxico, Head of the Department of Agricultural Economics, for his encouragement and support.

I am grateful to the Ministry of Agriculture of Turkey and the Department of Agricultural Economics, Oklahoma State University, for making my graduate program feasible.

Thanks are extended to Ms. Dixie Anne Mosier for her encouragement during this study and help in preparing this manuscript; to Mr. James Chang for programming the simulation model; to Ms. Eileen Garrison for typing the rough copy; to Ms. Grayce Wynd for typing the final draft; to Ms. Judy Hays for the figures, and to Ms. Raye Stucker for the tables.

Finally, special gratitude is expressed to my mother, Emine, and my father, M. Seyfeddin, for their encouragement, understanding, and support throughout my education program. I gratefully dedicate this dissertation to them.

## INTRODUCTION

## A. Need for the Study

Economic development plans are important at the state level. Robert S. Herman [15] indicates a great and growing need for improved, long-range economic and social programming by the states. ${ }^{1}$ Part of the need is related to increasing urbanization and other population movements, to changing structural social and economic conditions, to advancing technologies, and to increasing state and local government budgets. In addition, other pressures are generating demands for improving programming by state governments. Requirement for long-range program planning to qualify for federal planning is one of them. The Community Mental Health Facilities Act and Economic Opportunity Act are recent examples of this type of pressure. State governments are also being pushed into planning by local governments.

As local planning activities expand, local officials will become more aware of the need for broader planning efforts by the state... Too often a town and county finds its road-building program upset by a state decision to buy land for a recreation area, or for a new hospital, or for some other purpose which the local government was unable to anticipate in terms of probability, placement, or timing. [15, p. 143].

[^0]Neighboring states also pressure for planning as states become increasingly aware of the importance of coordinating their programs with neighboring states. Water supply, air pollution control, and transportation represent some of the examples of this nature where these are, in general, long-term projects. The case of Oklahoma supports all of these points made by Herman.

Economic projections are useful for economic planning. Through these projections, the direction of the economy is established and the need for resources can be determined. Projections are also necessary for evaluation of various development strategies. Selection of the strategy which satisfies the objectives with available resources can be determined through evaluation processes. Research provides information for regional plans and is needed to evaluate development programs. Research is needed for evaluating the programs in government, agriculture, and industry activities. The effects of various governmental decisions need to be evaluated through these studies.

There is very little research completed for Oklahoma which may be used to project State economic variables and to evaluate alternative development strategies. The economic and social changes which occurred from 1950 to 1960 in Oklahoma are analyzed by Charles H. Little [20]. Two input-output studies [21],[22] measured the interrelationships of industry sectors of the State economy and of three districts in the State. Another study [111] analyzed selected aspects of recent economic growth in Oklahoma. The most extensive study about the Oklahoma economy is completed by Gerald A. Doeksen and Dean F. Schreiner [7]. This is a simulation model of Oklahoma centered around input-output analysis. Different from the previous studies, this dynamic analysis
provides economic projections from 1963 to 1980 and can be useful in evaluating various development strategies. An economic impact approach was applied to compare economic variables in terms of generating income and employment and cost per job created or one million dollars generated.

The Oklahoma simulation model developed in this study is designed to satisfy four needs. First, projections of the state economic variables through 1985 are needed by state planners. Second, an analysis of human resource is needed for analyzing future manpower needs. Third, a method is needed to measure the impact of changes in the private sector. Fourth, there is a growing need for analysis of government programs.

## B. The Oklahoma Economy

Oklahoma is basically an agricultural state where grain and livestock production are equally important. Total farm marketings were $\$ 2,047,000,000$, and ranked 15 th among the states in 1973. Mineral production is also an important element of the Oklahoma economy. Petroleum and natural gas provide the greatest share in mineral production of the state, which was ranked sixth among the states in 1972. Median family income of Oklahoma was $\$ 7,720$, and it was ranked as 42nd in 1969. Percent of persons below the low income level was 18.8 and percent of families was 15.0 in 1969. Personal income per capita was $\$ 4,189$, which was below the United States average and ranked 37 th in 1973 [77].
C. The Objectives of the Study

The major objective of this study is to develop a social accounting
system for Oklahoma for 1967 and to utilize this information to develop an economic model for purposes of projecting economic variables and evaluating planning strategies. More specifically, the objectives are:
A. To develop a social accounting system for Oklahoma which inc1udes:

1. a transaction account,
2. a capital account,
3. a human resource account, and
4. a government account.
B. To develop a dynamic sịmulation model app1icable to Oklahoma which will:
5. project employment, population, income, revenue and other state economic variables from 1967 through 1985,
6. provide manpower analysis for each sector and for Oklahoma, and
7. provide a tool which can be used for analyzing the impact of alternative development strategies.
D. The Organization of the Study

Chapter II presents the Oklahoma social accounting system. Chapter III presents the interindustry account and the capital account. Chapter IV includes the human resource account and the government account. In Chapter V, the simulation model is developed and presented. Projections and discussions of economic variables (such as employment, income, revenue, etc.) and the manpower analysis are presented in Chapter VI. An illustration of how the model can be used to measure
the impact of a change in the economy is presented in Chapter VII. Summary, conclusions and implications are contained in Chapter VIII. Data sources are discussed in detail in Chapters III through V, and in Appendix A.

## CHAPTER II

THE OKLAHOMA SOCIAL ACCOUNTING SYSTEM

The Oklahoma social accounting system is an extension of Doeksen's system [4] which was adopted from Perloff and Leven's proposed model [40]. Stock-flow and flow-stock relationships are included in this model. ${ }^{1}$ Perloff and Leven find these relationships essential for most dynamic regional analyses. In this chapter, sector specification is discussed, followed by an overview of the Oklahoma social accounting system.

## A. Sector Aggregation and Data Sources

The base year of this study is 1967 because secondary data are more complete for this year than for any other recent year. Secondary data are used because collection of primary data requires much time and is also very expensive. Most of the data needed for the model are available in census and other government documents. ${ }^{2}$

The criteria used for aggregating the economy into a workable number of sectors are (1) the sectors' importance in Oklahoma economy, and

[^1](2) their consistency with available data as classified by the Bureau of Labor Statistics.

Agricultural activities are divided into two sectors: (1) livestock and livestock products, and (2) crops and other agricultural products. Crude oil mining is an important part of the Oklahoma economy; therefore, a separate sector for mining activity is included.

Aggregation of manufacturing sectors is necessary. Criteria used to aggregate manufacturing activity are (1) similarities among industries, and (2) their importance to the State's economy. Manufacturing industries are aggregated into nine sectors. These nine sectors are: (a) food and kindred products; (b) petroleum refining and related industries; (c) lumber and wood products, furniture and fixtures, and paper and allied products; (d) apparel and other finished products made from fabrics and similar materials, (e) printing and publishing and allied industries; (f) machinery, electrical machinery equipment and supplies; (g) transportation equipment; (h) primary metal industries, fabricated metal products except ordnance, machinery, and transportation equipment; and (i) all other manufacturing industries.

The service-type activities of the economy are combined into five sectors: (a) construction; (b) transportation, communication, and public utilities; (c) wholesale and retail trade; (d) finance, insurance, and real estate; and (e) services.

Each of these activities, previously described, represents one of the endogenous sectors of the model. The model also has five exogenous or final demand sectors. These are (a) federal government, (b) state and local government, (c) private capital formation, (d) households, and (e) exports. A complete listing of the endogenous and exogenous
sectors, along with the associated sector numbers which are referred throughout this study is presented in Table I.

## B. The Oklahoma Accounts

Oklahoma social accounting system includes four major accounts and is outlined as a flow chart in Figure 1. The accounts included in the system are a capital account, an interindustry account, a human resource account, and a government account. The interindustry account is the base of the system. Capital, human resource, and government accounts are directly related to the interindustry account.

## 1. The Interindustry Account

As outlined in Figure 1, the interindustry account of the 0klahoma social accounting system consists of three major parts: a transaction or interindustry flow table, a direct coefficients table, and a direct and indirect coefficients table. The transaction table forms the base of the interindustry account, and other tables are derived directly from it.

The transaction table represents a double entry accounting system. Reading down the colums of the endogenous sectors, purchases of the column sectors are determined. Likewise, reading across each row of the endogenous sectors, sales of each row sector are determined. Exogenous sectors are included in the final demand section. Exogenous sectors' purchases of goods and services from the producing sectors are included in this section. The primary input section consists of federal government, state and local government, imports, households, and depreciation. The amount of primary inputs purchased by the processing

Figure 1. The Oklahoma Social Accounting System
and final demand sectors are given as entries of each row sector in this section.

The direct or technical coefficients are obtained by dividing each entry of a column by the total input of that column sector. These coefficients indicate input requirements per dollar of output. They are relevant only for the processing sectors; therefore, they are computed only for 17 purchasing sectors. The direct and indirect coefficients indicate the total change which includes direct and indirect effects in input requirements as a result of a one dollar change in final demand.

## 2. The Capital Account

Oklahoma Capital analysis which is discussed in detail in Chapter III is formed around the capital coefficient matrix. The capital coefficients indicate the amount of capital goods required from each row sector for every dollar's worth of capital expenditures made by each column sector.

Capital-output ratios are defined as the ratio of the total cost of plant and equipment to output at capacity. These ratios are computed for the 17 endogenous sectors only. Capacity level of each sector is estimated by using employment data.

Capital coefficient matrix and the capital-output ratios are utilized along with output estimates to obtain the capital stock matrix. Multiplication of output estimates by the capital-output ratios yield the capital estimates by sector. Each sector's total capital is distributed to obtain the composition of each sector's capital stock, by the corresponding column of that sector's capital coefficient matrix. Each entry of the capital stock matrix indicates the total value of
capital goods produced by a row sector that is also invested by corresponding column sectors.

The capital unit matrix is derived from the capital coefficient matrix and the capital-output ratios. Every coefficient of this matrix indicates the amount of capital goods required by a column sector from every row sector to produce one unit of output capacity for that column sector. These coefficients are obtained by multiplying the capital coefficients of each sector and the capital-output ratio of that sector. To complete the capital analysis, depreciation rates need to be estimated. These coefficients are computed as the ratio of depreciation to the depreciable assets.

## 3. The Human Resource Account

The human resource analysis is important in a social accounting system. In this study, special emphasis is given to the human resource section. Oklahoma human resource analysis is formed around the labor coefficient matrix. The labor coefficients indicate the amount of labor required from each occupation group for every one unit change in the total employment of the column sector.

Output-employment ratios are defined as the value of output produced per laborer. These ratios are computed for the 17 endogenous sectors. Multiplication of the output estimates by the reciprocal of output-employment ratios (which are labor-output ratios) yields the sector employment matrix. The last two elements (federal government sector and state and local government sector) of sector employment matrix are obtained by using the previous year's employment. Each sector's total employment is distributed by the corresponding column
of that sector's labor coefficient matrix to obtain the composition of each sector's labor stock. Each entry of the labor stock matrix indicates the number of employees in each row occupation group that is working in column sector. Total employment by occupation matrix is obtained by row-wise summation of labor stock matrix. Each element of this column vector indicates the total number of employees in each occupation group.

Total employment by occupation matrix is utilized to estimate total Oklahoma employment which is used to determine Oklahoma population. Labor stock matrix is utilized to determine sector wage and salary rates and sector proprietor income rates. With these incomes and with separate estimation of property income, other labor income, and transfer payments, it is possible to compute total personal income. Disposable income is obtained by subtracting personal taxes from total personal income. Personal income per capita and disposable income per capita are calculated from total personal income, disposable income, and population information. Data sources and computation procedures are discussed in detail in Chapters IV and V.
4. The Government Account

A complete social accounting system should include a government section. In this study, government activities are analyzed in two sub-sections: federal government and state and local government (Figure 1). Federal government activities are brought together around two major points: federal government revenues and federal government expenditures. Individual income tax collections which are a part of total federal revenues are estimated separately so that disposable
income can be determined.

The second section of Oklahoma government account consists of state and local government activities. As in the federal government sub-section, state and local government activities are centered around two major points: state and local government revenues and state and local government expenditures.

State and local government revenues are studied in six categories which may be outlined as: (1) state sales tax; (2) individual and corporation income tax; (3) gasoline, fuels excise, and special fuels-use tax; (4) all other state and local taxes; (5) federal aid to the state and local government; and (6) all other revenues. State and local government expenditures are analyzed in five categories. These may be outlined as state and local government expenditures on:(1) education, (2) highways, (3) public welfare, (4) health and hospitals, and (5) others. Further discussion of the individual parts of this section is given in Chapters IV and $V$.

## CHAPTER III

THE INTERINDUSTRY ACCOUNT AND THE

CAPITAL ACCOUNT

## A. The Interindustry Account

The interindustry account is presented in three tables: a transaction or industry flow table, direct coefficients table, and direct and indirect coefficients table. The latter two tables are derived from the first one. W. H. Miernyk [26] provides good background information which might be helpful to review the basic theory of input-output analysis. Data sources, definitions, assumptions, and techniques used in constructing the interindustry flow matrix are presented in Appendix A. 1. The Interindustry Flow Table

The interindustry flow of goods and services (Table II) provides the base for analysis of the interindustry account. Column sectors of an interindustry flow table represent the consuming sectors, whereas row sectors represent the producing sectors.

The entries in each column indicate the purchases made by the column sector from the corresponding row sector. Thus, they represent the input structure of each consuming sector. For illustration purposes, consider the food and kindred products sector (sector 5) in Table II. The food and kindred products sector purchases $\$ 137,976,000$

INTERINDUSTRY FLOW TABLE, OKLAHOMA, 1967 (thousands of dollars)

worth of goods and services from the livestock and livestock products sector (sector 1 ), and $\$ 50,963,000$ from the crops sector (sector 2 ). The food and kindred products sector purchases \$354,000 and \$1,527,000 worth of goods and services from the mining sector (sector 3) and construction sector (sector 4), respectively, etc.

Entries in each row represent the values of goods and services sold to every purchasing sector. For example, consider the petroleum refining sector (sector 6) in Table II. Purchases of agricultural sectors from the petroleum refining sector are $\$ 6,002,000$ by the livestock and livestock products sector (sector 1 ); and $\$ 35,273,000$ by the crops sector (sector 2). The mining sector (sector 3 ) purchases $\$ 13,500,000$ and the construction sector (sector 4) purchases $\$ 22,156,000$ of goods and services from the petroleum refining sector, etc.

As can be deduced from Table II, only livestock and livestock products (sector 1), crops (sector 2), mining (sector 3), and petroleum refining (sector 6) sectors are exporting sectors and all others are importing sectors. Calculations of exports and imports are given in detail in Appendix A; however, it is useful to point out that the terms "exports" and "imports" are used to indicate the "net" values of exports and imports in this study.

## 2. Direct Coefficients

The direct coefficients are given in Table III. Entries in each column indicate the direct purchases of the column sector from each row sector per dollar's worth of output. These coefficients show only the first round effects of a change in output of a column sector on the sectors from which that sector purchases goods and services. Direct

coefficients are computed only for the endogenous sectors, since they are the only relevant ones. ${ }^{1}$ For example, consider the livestock and livestock products sector (sector 1). If output of the livestock and livestock products sector increases by one dollar, this increases purchases from the industries within the sector by 20.3 cents; purchases from the crops sector (sector 2) increase by 28.7 cents. Effects of this on purchases from the mining sector (sector 3) are very insignificant; less than one cent increase in purchases from the construction sector (sector 4) takes place. Increases in purchases from the manufacturing sectors are .6 cents from food and kindred products sector (sector 5); 1.2 cents from the petroleum refining sector (sector 6); and .2 cents or less from all manufacturing sectors (sector 7 through sector 13). The amount of increase is about 2.9 cents in the transportation, communication, and public utilities sector (sector 14); 20 cents in the wholesale and retail trade sector (sector 15); 1.2 cents in the finance, insurance, and real estate sector (sector 16); and 1.2 cents in the services sector (sector 17). This implies that the livestock and livestock products sector has a large direct relationship with firms within that sector and with the crops sector. The only manufacturing sectors having relatively importand direct relationships are food and kindred products and petroleum refining sectors.

## 3. Direct and Indirect Coefficients

The direct and indirect coefficients, given in Table IV, show the
$1_{\text {Table }}$ III meets stability conditions for the table of technical coefficients since (a) at least one column in the table adds up to less than unity, (b) no column in the table adds up to more than unity [26, p. 23].

total effects on input requirements as a result of one dollar change in sector final demand. Total effects include the indirect effects as well as the direct effects. ${ }^{2}$ Indirect effects indicate the chain of secondary changes. For illustration purposes, consider the livestock and livestock products (sector 1). A one-dollar change in final demand for products of the livestock sector causes a change of 20.3 cents as a result of direct interindustry transactions which is the first-round effect (Table III). A one-dollar change in final demand for products of the livestock sector causes a change of 25.8 cents as a result of total effects (Table IV). Since the value of change as a result of direct effects is 20.3 cents, the value of change as a result of indirect effects can be obtained only by subtracting this amount from the value of change as a result of total effects, which is 25.8 cents. In this way, 5.5 cents represents the indirect effects. The magnitude of the indirect effects on the crops sector (sector 2) as a result of a dollar change in the final demand for the products of the livestock seator can be obtained by subtracting 28.7 cents (Table III) from 37.5 cents (Table IV), which yields 8.8 cents, etc. The direct and indirect coefficients provide the basis for the simulation model. These coefficients are multiplied by final demand estimates to obtain the sectors' output estimates. Projections of all other economic variables are based on sector output estimates.

## B. The Capital Account

It is difficult to have an objective evaluation of alternative

[^2]development strategies without a capital account. This section discusses the capital account which is presented in six tables: capital coefficient matrix, sector capacity estimates, capital-output ratios, capital stock matrix, capital unit matrix, and depreciation rates. The capital account analysis of this study is based on Doeksen and Schreiner's extensive work about capital structure in Oklahoma. ${ }^{3}$

## 1. Capital Coefficient Matrix

The capital coefficient matrix of the Oklahoma capital analysis is represented in Table V. Reading down a column indicates the purchases of capital goods from producing sectors per dollar of investment by that column sector. For instance, for each dollar investment by the mining sector (sector 3 ), $\$ .00010$ of capital goods are purchased within itself and $\$ .01608$ of capital goods purchased from the construction sector (sector 4), etc. The largest purchases of capital goods and purchases by the mining sector (sector 3) are $\$ .61086$ from the machinery and electrical machinery sector (sector 10), \$. 18267 from the transportation equipment sector (sector 11), and $\$ .13700$ from the wholesale and retail trade sector (sector 15).

## 2. Capacity Estimates

A similar method to that developed by the Wharton School Econometrics Unit [17] is used to estimate capacity levels. Even though this is a simple method, it is considered as good as any other
${ }^{3}$ For a complete discussion of concept and definitions used in deriving the Oklahoma Capital Account, see [5].

method. ${ }^{4}$ Employment data are used as proxies for the production indices of Oklahoma in 1967 , since these are the best statistics available. Employment of each sector is averaged into quarterly figures. These are plotted on a graph, and peaks are determined. Each peak period is assumed to represent one hundred percent capacity. A straight line connecting peaks is used to describe capacity between peaks. If the latest peak has not been reached, extrapolation of the closest straight line is used to determine the capacity level for that specific period. Capacity estimates by sector are presented in Table VI.

## 3. Capital-Output Ratios

These ratios indicate the dollar value of capital required in order to obtain one dollar's worth of output. Since capital-output ratios are not available for Oklahoma, estimates of the U. S. capital-output ratios are used [101]. The average capital-output ratios are defined as total assets divided by total receipts.

Sector capital-output ratios are presented in Table VII. Type I capital-output ratios (column 1) reflect capital needs at average output, whereas Type II capital-output ratios (column 2) are defined as capital needs at capacity output levels. Consider the livestock sector (sector 1) as an example. Capital stock needs of the livestock sector must be increased by $\$ 1.20536$ to increase the sector's output by one

dollar. Type II ratios represent the capital-output ratios at capacity levels of output. They are obtained by multiplying the average capitaloutput ratios and the capacity estimates. They indicate the capital goods needed by each sector to increase the sector's output by a dollar when the sector's output is at the capacity levels. The livestock sector's need for capital goods when output is at capacity level is $\$ 1.09314$.

## 4. Capital Stock Matrix

The amount of capital in each sector is obtained by multiplying the capital output ratio (defined at capacity level output) by the estimated output at capacity. By multiplying the amount of capital in each sector by that sector's capital coefficients column, the composition of capital in each sector is obtained. The capital stock matrix of the Oklahoma model for 1967 is presented in Table VIII. Each entry represents the amount of capital goods produced by the row sector and invested in the column sector. For instance, in the construction sector (sector 4), total capital investment in 1967 is $\$ 179,901,000$. Of this investment, $\$ 371,000$ is from the mining sector (sector 3 ), $\$ 57,915,000$ from industries in that sector, $\$ 1,603,000$ is from the petroleum refining sector (sector 6), etc.

## 5. Capital Unit Matrix

Capital unit matrix is constructed by using the capital coefficient matrix and the capital output ratios. The coefficients of this matrix are computed by multiplying the capital coefficients of a sector (Table V) and the corresponding capital output ratio (Table VII). Each

coefficient of Table IX indicates the value of capital goods required from producing sectors (row sector) to produce one dollar's worth of additional output by consuming sectors (column sector) at capacity level. For instance, consider the crops sector (sector 2). For each additional dollar of output at capacity, the crops sector requires \$. 00103 worth of capital goods from the mining sector (sector 3), \$. 16121 worth of capital goods from the construction sector (sector 4), etc. This matrix is useful to compute the composition of required capital to increase output in a particular sector.

## 6. Depreciation Coefficients

The last component of this capital analysis consists of depreciation coefficients. These coefficients are estimated as the ratio of annual depreciation to total depreciable assets. U. S. Internal Revenue Service [102] data are used for these estimates. Depreciation rates, as listed in Table $X$, indicate the annual depreciation rate for various sectors from four to eleven percent.

## CHAPTER IV

## THE HUMAN RESOURCE ACCOUNT AND THE <br> GOVERNMENT ACCOUNT

A. The Human Resource Account

The human resource account is a vital portion of a simulation study. Manpower needs are increasing and changing over time, thus making this an important area for research input. The major matrices include labor coefficient matrix, output-employment ratios, sector employment matrix, labor stock matrix, sector wage and salary and proprietor employment matrix, total Oklahoma employment by occupation matrix, sector wage and proprietor income rates matrices, and sector wage and salary and proprietor income matrices.

1. Employment

Total employment in Oklahoma in 1973 was $1,064,000$ compared to 859,700 in $1960,944,100$ in 1967, and 974,000 in 1970. The rate of increase in employment has been larger than the rate of increase in population. The labor participation rate has increased recently, due mainly to more women joining the work force. Economic and social reasons are the main stimulators for this change. Components of the Oklahoma labor force for recent years are given in Table XI.

Employment in most sectors has increased over time. Agriculture,

TABLE XI
LABOR FORCE, OKLAHOMA, 1960, 1963, 1967-1973

| 1971 | 52.0 | 800.2 |  |  |  |  |

${ }^{1}$ Includes those unemployed as a result of labor disputes.
${ }^{2}$ Starting from 1970, the concept and estimating procedure have been changed.
${ }^{3}$ The source for these figures is Oklahoma Employment Security Commission, Handbook of Oklahoma Employment Statistics, 1958-1972, pp. 18-20.

Source: Oklahoma Emp1oyment Security Commission, Handbook of Oklahoma Employment Statistics, 1973.
mining, and federal government are the sectors where decreases have occurred. Labor force, total employment, self-employment, and nonagricultural wage and salary employment have increased.
a. Labor Coefficient Matrix. The labor coefficient matrix is presented in Table XII. This table includes labor coefficients for the 17 endogenous sectors, federal government sector, and state and local government sector. Each coefficient indicates the amount of change in labor requirements in each occupation group as a result of one unit change in the total employment of each column sector. For example, if the total employment of construction sector (sector 4) increases by one unit, this increases the employment requirements from engineers (occupation group 1) by .00602; scientists (occupation group 2) by .00022; technicians (occupation group 3) by .00411; etc. Total wage and salary employment increases by .65495, and the total proprietor employment by . 34505.

The elements of the labor coefficient matrix are derived from unpublished data provided by the Oklahoma Employment Security Commission [35]. Industry-occupation matrices for Oklahoma provide the total employment in 1970 in each sector by occupation and component. Rows of each sector's industry-occupation matrix distinguish 440 occupations in the eight-digit statistical industry code (SIC), whereas columns include private wage and salary, unpaid family, self-employed, federal government, state government, and local government employment. For this study, the 440 occupations are aggregated to $29 .^{1}$ In addition, unpaid family and self-employed workers are aggregated to obtain the
$1_{\text {For }}$ information relating to the manner in which occupations are aggregated, see Appendix B.

proprietorship employment. Federal government and state and local governments are analyzed separately; thus, there is an industryoccupation matrix for each endogenous sector and for each government sector.

The labor coefficient of each occupation group is obtained by dividing the number of employees in each occupation group by the total employment in each sector. The coefficient for the proprietorship employment in each sector is obtained by dividing the total proprietorship employment by the total employment in each sector. Total proprietorship employment in each sector is obtained by adding the number of proprietors in each occupation of each sector.
b. Output-Employment Coefficients. Output-employment coefficients indicate the value of output produced by each employee in each sector. They are obtained by dividing sector's output by sector's employment, and are presented in Table XIII.

Comparing the output-employment ratios found in Table XIII indicates that the petroleum refining sector (sector 6) has the highest output-employment ratio at $\$ 96,432$. This is a result of the high degree of capital intensity in this sector. Food and kindred products sector (sector 5) is the second highest with $\$ 38,655$. Next, in order of magnitude, are the mining sector (sector 3), and finance, insurance, and real estate sector (sector 16) with $\$ 28,161$ and $\$ 25,536$, respectively.
c. Sector Employment Matrix. The sector employment matrix is presented in Table XIV. Each entry indicates the total employment (wage and salary employment plus proprietor employment) in that

Oklahoma Employment Security Commission, IndustryOccupation Matrices for Oklahoma, 1970.
sector. For example, in 1967, employment was 15,760 in the food and kindred products sector (sector 5). The sectors with the largest employment according to the model sector's specification are the wholesale and retail trade sector, services sector, and state and local government sector.
d. Labor Stock Matrix. The labor stock matrix presented in Table XV indicates the occupational mix of employment by sector. Each element of the matrix is obtained by multiplying sector employment by the column of labor coefficients for that sector from Table XII.

Each entry indicates the number of employees working in that occupation in each sector. For example, the mining sector (sector 3) has 2,304 engineers (occupation group 1); 1,337 scientists (occupation group 2); 1,251 technicians (occupation group 3); etc. Total wage and salary employment in the mining sector is 41,000 ; total proprietor employment is 2,175; and total employment is 43,175 .
e. Total Oklahoma Employment by Occupation Matrix. Total Oklahoma employment by occupation in 1967 is given in Table XVI. Each entry in this column vector is obtained by adding the number employed in that occupation across all sectors. They indicate the total number of employees in each occupation group, total wage and salary employment, and total proprietor employment. Total Oklahoma employment can be determined by summing total wage and salary employment and total proprietor employment.

## 2. Population

Oklahoma population has been increasing continuously since 1950. There were $2,328,000$ people living in Oklahoma in 1960, compared to

| 28. | Public service workers (10) | 43,455 |
| 29. | Laborers (00) | 46,874 |
|  | Total wage and salary | 725,300 |
|  | Total proprietor | 218,800 |
|  | Total employment | 944,100 |

$2,489,000$ in $1967,2,567,000$ in 1970 , and $2,709,000$ in 1974. The direction of migration has changed. In the decade of 1950s, the State was experiencing net outmigration. However, net immigration has occurred recently. Oklahoma's gain in population by migration totaled 81,000 in 1974 [36].

Oklahoma population analysis is based on total employment in Oklahoma. Assuming perfect mobility of labor and full employment, population is estimated by considering a specific portion of the population is employed. A ratio of population to total employment is obtained for the base year, first. Then this ratio is multiplied by the estimated total employment. Since the proportion of population which is employed has been increasing, a coefficient is incorporated into the estimation procedure, making necessary adjustments annually by changing the 1abor participation.

## 3. Income

This section of the human resource analysis includes sector wage and salary rates and proprietor income rates, sector wage and salary and proprietor incomes, total personal income, personal income per capita, disposable income, and disposable income per capita.
a. Sector Wage and Salary Rates and Proprietor Income Rates,

These ratios indicate wage and salary rates and proprietor income rates per employee by sector, and are computed by using the income figures from Table XVII and employment figures from Table XV. Sector wage and salary rates and proprietor income rates are obtained by dividing each sector's wage and salary payments and proprietor income by wage and

*Wage and salary incomes ot agricultural and manufacturing sectors are distributed by wage and salary employment.
** Farm and non-farm proprietor incomes are distributed into included sectors by using the profits of sole proprieto ship and partnership of the corresponding sectors.
source: Estimates were obtained from U. S. Department of Treasury, Statistics of Income: 1967 Business Income Tax Returns, and :: S. Department of Conmerce, Survey of Current Business, August, 1970.
salary employment and proprietor employment of the same sector. These ratios are presented in Table XVIII. Sector wage rates are presented in column (1) and are presented for the endogenous and government sectors. Column (2) displays sector proprietor income rates for the endogenous sectors. Federal government pays the highest salary per employee at $\$ 11,529$. Mining sector (sector 3 ) pays the highest wages and salaries per employee among endogenous sectors at $\$ 7,585$. Following closely is the transportation, communication, and public utilities sector (sector 14 ) at $\$ 6,869$. Petroleum refining sector (sector 6) shows the highest proprietor income rates at $\$ 11,905$. Primary and fabricated metal products sector (sector 12) and finance, insurance, and real estate sector (sector 16) are found to have the following highest proprietor income rates at $\$ 8,061$ and $\$ 8,033$, respectively.
b. Sector Wage and Salary and Proprietor Income. Table XVII displays the sources of wage and salary and proprietor income. The first column of this table indicates the dollar value of wage and salary income by sector. The second column of the same table presents the percentage distribution of total wage and salary income by sectors. Federal government has the largest share with 16.91 percent, with the wholesale and retail sector next with 16.47. They are followed by state and local government and services sectors, with 12.23 percent and 10.21 percent, respectively.

The third column of Table XVII displays the total value of proprietor income by sector. The fourth column of the same table indicates the percentage distribution of each sector's share. Services sector is the largest at 32.82 percent. It is followed by the crops sector with

TABLE XVIII
WAGE AND SALARY RATES AND PROPRIETOR INCOME RATES, OKLAHOMA, 1967

|  | Sectors S | Wage and Salary Rates | Proprietor Income Rate |
| :---: | :---: | :---: | :---: |
|  |  | (1) | (2) |
| 1. | Livestock | 1,579 | 2,868 |
| 2. | Crops | 1,579 | 2,868 |
| 3. | Mining | 7,585 | 865 |
| 4. | Construction | 6,062 | 3,149 |
| 5. | Food and kindred products | 6,297 | 5,053 |
| 6. | Petroleum refining and related industries | s 6,295 | 11,905 |
|  | Lumber and wood, furniture and fixtures, paper and allied products | 6,294 | 4,724 |
|  | Apparel and other finished products made from fabrics and similar materials | 6,296 | 5.293 |
| 9. | Printing, publishing, and allied industries | 6,300 | 3,193 |
|  | Machinery, electrical machinery equipment and supplies | 6,298 | 6,621 |
| 11. | Transportation equipment | 6,294 | 1,921 |
|  | Primary and fabricated metal products industries except ordnance, machinery, and transportation equipment | 6,298 | 8,061 |
| 13. | Miscellaneous and all other manufacturing industries | 6,299 | 2,913 |
| 14. | Transportation, communication, and public utilities | 6,869 | 3,634 |
| 15. | Wholesale and retail trade | 4,249 | 3,626 |
| 16. | Finance, insurance, and real estate | 5,118 | 8,033 |
| 17. | Services | 4,161 | 6,634 |
|  | Federal government | 11,529 | - |
|  | State and local government | 4,243 | - |

19.18 percent, wholesale and retail sector with 16.69 percent, and livestock sector with 14.66 percent.

The last two columns of Table XVII present the distribution of total civilian income among sectors and each sector's percentage share in it. In total civilian income, wholesale and retail sector has the lead with $\$ 812,039,000$ and 16.51 percent of total civilian income. Services sector with $\$ 697,233,000$ and 14.17 percent, federal government with $\$ 686,000,000$ and 13.95 percent and state and local government with $\$ 496,000$ and 10.08 percent follow it, in that order.
c. Personal Income Analysis. This section of the human resource account is concerned with total personal income, personal income per capita, disposable income, and disposable income per capita.

Total personal income in Oklahoma increased from $\$ 6,664,000,000$ in 1967, to $\$ 11,558,000,000$ in 1973. Data in Table XIX indicates that every sector's wage and salary payments increased substantially except federal military payments where the increase was minor. Proprietor income, other labor income, property income, and transfer payments also realized significant increases. Actually, all of these, other than property income, more than doubled from 1967 to 1973. It is useful to make a point before closing this analysis. Some sectors--such as agricultural and mining--experienced exceptionally high prices for their products in 1973. As a result, proprietor's income in these sectors increased substantially.

Total personal income is estimated by summation of five components and subtraction of personal contributions to social insurance. The five components are: wage and salary income,

TABLE XIX

*Starting from 1973, the data are presented differently. For every sector other than farms and government, under wage and salary heading, total payments are listed instead of wage and salary payments.

Source: U. S. Department of Commerce, Survey of Current Business, various issues, 1970-1974.
property income, transfer payments, other labor income and proprietor income.

Personal income per capita is defined as total personal income divided by population. This measure might be a better indication to trace the well-being of an economy than total personal income. Per capita personal income in Oklahoma has been increasing continuously--it was $\$ 2,712$ in $1967, \$ 3,127$ in 1969 , and $\$ 3,553$ in 1971 , compared to $\$ 4,340$ in 1973 [82]. Total personal income estimate is divided by population estimate to estimate personal income per capita. Disposable income is obtained by subtracting personal taxes from total personal income. Disposable income per capita is obtained by dividing disposable income by population.

## B. The Government Account

Government activities are analyzed in two groups: federal government activities and state and local government activities. Revenues and expenditures of federal government and state and local government and the procedures in estimating these are discussed in the following sections.

## 1. Federal Government Activities

Federal government revenues in Oklahoma consist of federal government taxes collected in Oklahoma. Federal tax collections are grouped in three major parts: individual income tax, corporation income tax, and all other federal taxes. Among these individual income tax collections are the largest component and have the highest rate of increase. Federal individual tax collections were 89.9 percent higher
in 1973 compared to the collections in 1967. Corporation income tax collections indicated declines for 1968-1970. They were about the same level in 1971 and in 1972 as in 1967. In 1973, corporation tax collections increased and were 6.3 percent higher than in 1967. All other tax collections indicated slight drops in 1969 and 1970, but were 29.9 percent higher in 1973 than in 1967. Total federal tax collections increased 58.8 percent from 1967 through 1973. Tax collections for each group for each year and the total are given in Table XX.

TABLE XX

FEDERAL GOVERNMENT TAX COLLECTIONS, OKLAHOMA, 1967-1973

| Year | Individual <br> Income Tax | Corporation <br> Income Tax | A11 Other Federal <br> Tax Co1lections | Total Federal <br> Tax Co1lections |
| :---: | :---: | :---: | :---: | :---: |
|  | $(\$ 000)$ | $(\$ 000)$ | $(\$ 000)$ | $(\$ 000)$ |

|  |  |  |  |  |

Source: Internal Revenue Service, Annual Report, various issues, 1967-1973.

Total federal government tax collections are estimated by regression analysis with total personal income as the independent variable.

Individual income tax collections are estimated separately with total employment as the independent variable. ${ }^{2}$

Total federal government expenditures in Oklahoma increased 18.3 percent from 1968 to 1972. Table XXI shows the federal government outlays in Oklahoma in recent years. Federal government expenditures in Oklahoma are estimated by a trend method.

TABLE XXI

TOTAL FEDERAL OUTLAYS, OKLAHOMA, 1967-1972

| Year | $\left.\begin{array}{c}\text { Federal } \begin{array}{c}\text { Government Outlays } \\ \text { in Oklahoma }\end{array} \\ \hline\end{array}\right](\$ 000)$ |

Source: U. S. Department of Commerce, National Technical Information Service, Federal Outlays in Oklahoma in 1968.
${ }^{2}$ Data were converted to constant 1967 prices for the regression procedure. The equations and relevant statistical information about the equations are presented in Chapter $V$.

## 2. State and Local Government Activities

State and local government revenues are composed of three types of sources: state and local government tax collections, federal aid to the state and local governments, and all other state and local government revenues.

Tax collections of state and local governments include state sales tax, gasoline and fuels excise taxes, income tax, and all other state and local taxes. Collections from 1967 through 1974 are presented in Table XXII. Among these, state sales tax collections increased by 86.1 percent, gasoline and fuels excise taxes increased by 30.2 percent, and individual and corporation income taxes increased by 205.0 percent from 1967 through 1974. The greatest single jump took place in 1972 when the tax rates were raised as a result of the "Oklahoma Income Tax Act " which was effective after December 31, 1970.

Total tax collections of state and local governments are given in the first column of Table XXIII. In the six-year period of 1967-1972, total tax collections increased by 63.1 percent. Rates of increase in the second, third, and fourth columns of Table XXIII for the same period are obtained as 56.0 percent, 68.7 percent, and 62.2 percent for federal aid, all other revenues, and total revenues, respectively.

Each component of state and local government revenues is estimated by using a simple regression equation. Total personal income is the independent variable used to estimate state sales taxes and individual. and corporation income taxes. Personal income per capita is the independent variable utilized for estimation of gasoline, fuels excise, and special fuels use tax; other state and local government taxes; federal

aid to the state and local government; and other state and local government revenues. ${ }^{3}$

Major state and local government expenditures are: education expenditures, highway expenditures, public welfare expenditures, health and hospital expenditures, and all other state and local government expenditures. These are given in columns (1) through (5) of Table XXIV. The last column of the same table indicates the total value of state and local expenditures. The rates of increase in state and local expenditures are:education by 42.1 percent, highway by 27.5 percent, public welfare by 47.0 percent, health and hospital by 91.9 percent, and all other expenditures by 83.3 percent from 1967 to 1972. Total expenditures rose 52.1 percent for the same six-year period.

Each expenditure component is estimated by a simple regression equation. State and local government expenditures on: education, health and hospitals, and others are estimated by using lagged value of total personal income as the independent variable; highways are estimated by using lagged value of gasoline and fuels excise tax as the independent variable; and public welfare are estimated by using the lagged value of personal income per capita as the independent variable. ${ }^{4}$
$3^{\text {These }}$ equations and relevant statistical information about the equations are presented in Chapter $V$.
${ }^{4}$ For the equations, their discussion and relevant statistical information about the equations see Chapter V.

## CHAPTER V

## THE SIMULATION MODEL OF THE OKLAHOMA ECONOMY

Simulation models have been employed in regional development research since the mid 1950s. Availability of the digital computer has increased the application on this type of empirical tool. With the addition of more and more relationships, more complicated models are being solved more easily. In the first part of this chapter, several recent simulation studies which are based on input-output technique are reviewed. This section also includes a discussion of the differences of this study from previous models. In the latter part of the chapter, the Oklahoma Simulation Model is discussed in detail.
A. Previous Simulation Studies

The Iowa State study by Maki, Suttor and Barnard [24] was one of the first regional simulation studies based on the input-output model. Twenty-three major equations of this study described the current economic conditions in Iowa. These included derivation of final demand, estimation of sector output, sector employment, value added, total personal income, and disposable income. Another set of equations provided useful information about the functioning of the model. These auxiliary equations included ten major equations and estimated such variables as imports, exports, federal tax collections, gross area product, population, total labor force, and total employment. A11 of these equations
were arranged in a recursive sequence. Simulation runs were performed over the 1954-1974 period. Several experimental runs were made about labor productivity and export demand.

Unpublished Ph.D. dissertations by Mullendore [28] and MacMillan [23] are versions of the Maki, Suttor, and Barnard study. Mullendore, in his study, tried
...to develop procedures for projecting region's economy and people under a variety of alternative assumptions with respect to certain variables in the model [28, p. 45].

Behavioral and definitional equations were utilized to accomplish the objectives. This model accounted for feedback and time-related relationships in the Iowa economy. The main contribution of this study was the demographic sector whose purpose was:
...to account for changes in characteristics of the population which influence the economy. This is accomplished in the present study by accounting for population increases and decreases by age groups over time [28, p. 52].

MacMillan's [23] major objective was:
...the preparation of procedures for producing information to facilitate public service system performance by individual agencies and other governmental departments $[23, \mathrm{p} .3]$.

This study also presented a methodology to permit the evaluation of the impact of alternative public service programs for development. Specification of area and sub-area public service and income inequalities and the estimation of state funds required to equalize education services in Iowa planning areas were analyzed. Furthermore, this economic development model was used for experimentations for appraisal of state aid to local education.

Doeksen [4] developed a model similar to that of Maki, Suttor, and Barnard [24] for the Oklahoma economy. His input-output model consisted
of twelve endogenous and five exogenous sectors. The major contribution of this study was the addition of the capital sector. Capital coefficients for Oklahoma were developed. Also sector capacity levels, capital-output ratios, capital unit matrix, and capital stock matrix were included. This model was used to simulate over the 1963-1980 period. Short-run, intermediate-run, and long-run impacts of one million dollar investment in each sector were investigated in terms of new employment and income. This study also investigated the cost of creating employment for 100 persons in each sector and minimizing investment per million dollars of additional income.

Ekholm [9] developed a simulation model to estimate the impact of declining groundwater and petroleum resources for the Texas and Oklahoma Panhandle areas. Different from previous studies, this model was derived primarily by the supply of mined resources. Groundwater, crude oil, and natural gas have an impact on the regional economy. By assuming the agriculture, the petroleum, and the agricultural and petroleum supply related sectors are the primary driving force in the economy, Ekholm's model is an attempt to trace the impact of mined resources production on the regional economy. Household expenditures were estimated by utilizing income elasticities. This model covered the 19672010 period.

A recent simulation study was completed by a research team from Michigan State University with a U.S.A.I.D. contract [13]. The objective of this study was
...to develop the general simulation approach to studying agricultural development to a point where it would be applicable and operational $[13, p . v]$.

The "population model" was one of the major components of this
study and it was utilized to simulate the growth of the population in each region for the simulation period. The demand for subsistence calories in every crop area of each region and the demand for food staples purchased through the cash market were determined by the interaction of this model with the agricultural simulation model. The "population model" also determined the supply of agricultural labor available by crop area in each region, the total population in the agricultural and non-agricultural sector by region, and the number and growth rate of the farmers in each crop area in each region. The model had three dimensions: occupation, sex, and age coharts. Occupation was considered for only agricultural, non-agricultural, and unemployable. Population coharts which were updated by the model every three years, consisted of 27 three-year groups.

The Susquehanna River Basin study [14] is a widely-cited dynamic regional simulation model which used a set of simultaneous differential equations to describe the current economic conditions. Economic activity was specified in terms of employment: positive or negative feedback loops tied the employment and the demographic sectors together. The "driving force" of this model was market area demand which was operating through export industry employment.

Another study by Miernyk, et al. [27] developed a simulation model of the West Virginia economy. The central focus of this study, whose data were obtained by personal interviews with a sample of establishments, was the use of an input-output model to simulate certain aspects of economic development. The process of structural change in an economy was viewed in a dynamic setting. The climax of the analysis of structural change was given as follows:
...the important point is that peak levels of output will occur in the industries that are major suppliers of capital goods to the simulated sectors before the latter go into production [27, pp. 164, 165].

This study underwent the analysis of the costs and the benefits of a development subsidy--namely, for the sulfuric acid industry. Use of multipliers was emphasized as being useful in regional development planning; however, a special caution was given to their interpretations. Several other simulation studies can be added to the list. Some of these are Byerlee and Halter [1]; Holloway [16]; Tung, MacMillan, and Framingham [45] ; etc. All of these are similar to one or more of the studies mentioned earlier.

Oklahoma Simulation Model is most closely related to the Doeksen [4] study. Sectors' outputs of Oklahoma Simulation Model are estimated through final demand sectors. Household sector's purchases are estimated by using the lagged value of disposable income which is determined endogenously. This is a somewhat similar procedure to that of Ekholm [9]. As differences from the previous studies, Oklahoma Simulation Model incorporated the government account and the expanded human resource account into the model. Government sectors' revenues and expenditures are estimated by utilizing regression equations. These are also disaggregated into several components to obtain the best possible estimates. The major contribution of this study lies in the human resource account. Labor coefficients of Oklahoma are developed in this section. Sectors' employments are obtained by occupational groups. Human resource needs of Oklahoma are studied by sector and as total for the State. By disaggregating the manufacturing activity into nine sectors, the problem of aggregation is somewhat eased. These additions and the
rest of the model are discussed in detail in the following section.

## B. The Oklahoma Simulation Model

The Oklahoma Simulation Model is a recursive model involving 62 major equations and is built around the input-output system. The equations which estimate final demand, determine sector output and project state economic variables are discussed in detail. The complete listings of variables, matrices, and scalars are presented in Tables XXV, XXVI, and XXVII, respectively. Variables are presented in letters, brackets for vectors and parentheses for scalars, matrices by the capital letter $A$, and scalars by the lower-case a. The flow chart which is presented in Figure 2 helps explain the estimates of output. Various State economic variables are obtained by using final demand estimates. All monetary variables, unless otherwise indicated, are in thousands of dollars.

## 1. Projecting Final Demand

First, each final demand component needs to be estimated. Then, total final demand can be estimated by summing all of these components. Final demand sectors include private capital formation, household demand, export demand, and purchases made by federal government and state and local government.
a. Private Capital Formation. Composition of new investment is obtained by multiplying the capital coefficient matrix by the column vector of total investment. The column vector of total investment is obtained by summing three separate column vectors which are (1) new

TABLE XXV

VARIABLES IN OKLAHOMA SIMULATION MODEL

| Variable | Description |
| :---: | :---: |
| $[\mathrm{In}]_{\mathrm{t}}$ | Column vector of new plant and equipment investment in year t |
| $\left[\mathrm{X}^{\mathrm{d}}\right]_{t}$ | Column vector of sector output in year $t$ |
| $[\mathrm{K}]_{\mathrm{t}}$ | Column vector of capital stock at the beginning of year $t$ |
| $[\mathrm{In}]_{t}$ | Column vector of new plant and equipment investment made during year $t$ |
| $[\mathrm{Ir}]_{\mathrm{t}}$ | Column vector of replacement investment in year $t$ |
| $[I h]_{t}$ | Column vector of household expenditures on residential housing in year $t$ |
| $[I]_{t}$ | Column vector of total investment in year $t$ |
| $[\mathrm{CA}]_{\mathrm{t}}$ | Column vector of composition of new investment in year $t$ |
| $\left(\mathrm{LDI}_{t}\right.$ | Lagged percentage change in disposable income in year $t$ |
| (DI) $_{t}$ | Disposable income in year $t$ |
| $\left[C_{J}\right]_{t}$ | Column vector of personal consumption demand by sector in year t |
| $[E n]_{t}$ | Column vector of export demand for non-durables in year $t$ |
| $[E d]_{t}$ | Column vector of export demand for durables in year $t$ |
| $[E t]_{t}$ | Total export demand in year $t$ |
| $[T F E]_{t}$ | Column vector of total federal government purchases in Oklahoma in year t |
| $(E E)_{t}$ | State and local government expenditures on education in Oklahoma in year t |
| $(T P I)$ | Total personal income in Oklahoma in year $t$ |
| $(\mathrm{HE})_{t}$ | State and local government expenditures on highways in Oklahoma in year $t$ |
| $(\mathrm{GT})_{t}$ | Gasoline and fuels excise and special fuels use tax in Oklahoma in year $t$ |

TABLE XXV (Continued)

| Variable | Description |
| :---: | :---: |
| $\left.{ }^{(P W)}\right)_{t}$ | State and local government expenditures on public welfare in Oklahoma in year $t$ |
| $\left.{ }^{(P I P}\right)_{t}$ | Personal income per capita in Oklahoma in year $t$ |
| ${ }^{(H H)}{ }_{t}$ | State and local government expenditures on health and hospitals in Oklahoma in year $t$ |
| ${ }^{(O E)}{ }_{t}$ | State and local government expenditures on others in Oklahoma in year $t$ |
| $\left.{ }^{(T S E}\right)_{t}$ | Total state and local government expenditures in Oklahoma in year $t$ |
| $[\mathrm{TSE}]_{\mathrm{t}}$ | Column vector of total state and local government purchases in Oklahoma in year $t$ |
| $[z]_{t}$ | Column vector of total final demand in Oklahoma in year t |
| $\left[\mathrm{OCM}_{j}\right]_{t}$ | Occupation-component matrix for $j^{\text {th }}$ sector in year $t$ |
| $[\mathrm{LO}]_{t}$ | Column vector of labor-output coefficients in Oklahoma in year $t$ |
| $]_{t}$ | Column vector of available labor by sector in year $t$ |
| $\left[x^{L}\right]_{t}$ | Maximum sector output due to labor restriction in year t |
| $\left[\mathrm{x}^{\mathrm{c}}\right]_{t}$ | Maximum sector output due to capital restriction in year $t$ |
| $\left[L^{e}\right]_{t}$ | Column vector of sector employment in year $t$ |
| (E) ${ }_{t}$ | Total employment in endogenous sectors in year $t$ |
| $\left(L_{j}^{e}\right)_{t}$ | $j^{\text {th }}$ sector's total employment in year $t$ (or $j^{\text {th }}$ element in the column vector of $\left[\mathrm{L}^{\mathrm{e}}\right]_{t}$ ) |
| $\left[\mathrm{OCM}_{\mathrm{j}}\right]_{\mathrm{t}-1}^{\mathrm{t}}$ | Occupation-component matrix for needed labor by sector from year $t-1$ to year $t$ |
| $[\mathrm{OCM}]_{t}$ | Occupation-component matrix for the endogenous sectors of Oklahoma in year $t$ |
| $\left[L^{W} L^{p}\right]_{t}$ | Matrix of wage and salary and proprietor employment by sector for the endogenous sectors of Oklahoma in year $t$ |

TABLE XXV (Continued)

| Variable | Description |
| :---: | :---: |
| $\left[L_{w} L_{p}\right]_{t}$ | Row vector of total wage and salary and proprietor employment of the endogenous sectors of Oklahoma in year $t$ |
| $\left[\mathrm{L}_{\mathrm{f}}\right]_{\mathrm{t}}$ | Column vector of federal government employment by occupation in Oklahoma in year $t$ |
| ${ }^{(T E)}{ }_{t}$ | Total Oklahoma employment in year t |
| ${ }^{(P)}{ }_{t}$ | Total Oklahoma population in year $t$ |
| [WS] ${ }_{t}$ | Column vector of wage and salary payments in year $t$ |
| $\left[\mathrm{L}^{\mathrm{w}}\right]_{\mathrm{t}}$ | Column vector of wage and salary employment in year $t$ |
| $\left[\mathrm{Y}^{\mathrm{P}}\right]_{t}$ | Column vector of proprietor income in year t |
| $\left[L^{p}\right]_{t}$ | Column vector of proprietor employment in year t |
| (FS) ${ }_{t}$ | All governmental wages and salaries in Oklahoma in year t |
| (AF) ${ }_{t}$ | Military payroll in Oklahoma in year $t$ |
| $\left(Y^{T}\right)_{t}$ | Total transfer payments in Oklahoma in year $t$ |
| $\left(\mathrm{Y}^{\mathrm{Py}}\right)_{\mathrm{t}}$ | Total property income in Oklahoma in year t |
| (OY) ${ }_{t}$ | Total other labor income in Oklahoma in year t |
| $[\mathrm{v}]_{\mathrm{t}}$ | Column vector of value added in Oklahoma in year $t$ |
| $\left(X^{g}\right)_{t}$ | Gross state product in Oklahoma in year t |
| $(T F R)_{t}$ | Federal government tax collections in Oklahoma in year $t$ |
| (IIT) $_{t}$ | Federal individual income tax collections in Oklahoma in year t |
| ${ }^{(S T)}{ }_{t}$ | State sales tax collections in Oklahoma in year $t$ |
| (GT) $_{t}$ | Gasoline and fuels excise and special fuels use tax collections in Oklahoma in year $t$ |
| $\left.{ }^{(I T}\right)_{t}$ | Individual and corporation income tax withheld by the State in Oklahoma in year $t$ |
| $\left.{ }^{(O T}\right)_{t}$ | A11 other taxes collected by state and local government in Oklahoma in year $t$ |

| Variable | Description |
| :---: | :---: |
| ${ }^{(F A)}{ }_{t}$ | Federal aid to state and local government in Oklahoma in year t |
| ${ }_{(O R)}^{t}$ | Other revenues to state and local government in Oklahoma in year $t$ |
| $(\mathrm{TSR})_{t}$ | Total state and local government revenues in Oklahoma in year t |
| $(\mathrm{DI}){ }_{\mathrm{t}}$ | Disposable income in Oklahoma in year $t$ |
| $\left.{ }^{(D I P}\right)_{\mathrm{t}}$ | Disposable income per capita in Oklahoma in year t |
| $\left[\mathrm{L}_{\mathrm{s}}\right]_{\mathrm{t}}$ | Column vector of state and local government employment by occupation in Oklahoma in year $t$ |
| $[W S E]_{t}$ | Total wage and salary employment by occupation in Oklahoma in year $t$ |
| $[\mathrm{OCM1}]_{\mathrm{t}}$ | Column vector of wage and salary employment by occupation for the endogenous sectors of Oklahoma in year $t$ |
| $\left(L_{p}\right)_{t}$ | Total proprietor employment in Oklahoma in year $t$ |

TABLE XXVI

MATRICES IN OKLAHOMA SIMULATION MODEL

| Matrix | Description |
| :---: | :---: |
| $\mathrm{A}_{1}$ | Diagonal matrix of average capital-output ratios |
| $\mathrm{A}_{2}$ | Diagonal matrix of one plus annual rate of change in capitaloutput ratios |
| $\mathrm{A}_{3}$ | Diagonal matrix of depreciation rates |
| $\mathrm{A}_{4}$ | Diagonal matrix of one plus annual rate of change in households' residential housing expenditures |
| $\mathrm{A}_{5}$ | Capital coefficient matrix |
| $\mathrm{A}_{6}$ | Diagonal matrix of estimated income elasticities |
| $\mathrm{A}_{7}$ | Diagonal matrix of one plus annual growth rate of nondurables |
| ${ }^{\text {A }} 8$ | Diagonal matrix of one plus annual growth rate of durables |
| ${ }^{4} 9$ | Column vector whose elements are proportions of total state and local government purchases by sector in Oklahoma |
| ${ }^{\text {A }} 10$ | Direct and indirect coefficient matrix |
| ${ }^{\text {A }} 11$ | Diagonal matrix of labor force-employment ratios |
| ${ }^{\text {A }} 12$ | Diagonal matrix of one plus annual growth rate of employment |
| ${ }^{\text {A }} 13$ | Diagonal matrix where each element is reciprocal of corresponding labor-output coefficient |
| ${ }^{\text {A }} 14$ | Diagonal matrix of one plus annual rate of change in $\mathrm{A}_{13}$ |
| ${ }^{\text {A }} 15$ | Diagonal matrix of capital-output ratios defined at capacity levels |
| $\mathrm{A}_{16}$ | Diagonal matrix of one plus annual change in labor-output coefficients |
| ${ }^{\text {A }} 17$ | Diagonal matrix where elements are representing the corresponding elements of column vector of sector output |
| ${ }^{\text {A }} 18$ | Diagonal matrix of sector wage and salary rates |

TABLE XXVI (Continued)

| Matrix | Description |
| :--- | :--- |
| $A_{19}$ | Diagonal matrix of one plus annual growth rate of wages and <br> salaries by sector |
| $\mathrm{A}_{20}$ | Diagonal matrix of sector proprietor income rate |
| $\mathrm{A}_{21}$ | Diagonal matrix of one plus annual rate of change in pro- <br> prietor income |
| $\mathrm{A}_{22}$ | Diagonal matrix of the ratio of value added to output |

TABLE XXVII
SCALARS IN OKLAHOMA SIMULATION MODEL

| Scalar | Description |
| :---: | :---: |
| $a_{1}, a_{2}$ | Weights of percentage change in disposable income for previous three years |
| $a_{4}$ | One plus annual growth rate in federal government expenditures |
| $a_{5}$ | One plus annual rate of change in federal government employment |
| $a_{6}$ | One plus annual rate of change in state and local government employment |
| $a_{7}$ | Population-employment ratio in Oklahoma |
| $\mathrm{a}_{8}$ | One plus annual rate of change in population-employment ratio |
| $\mathrm{a}_{9}$ | Wage and salary rate of state and local government employees |
| $\mathrm{a}_{10}$ | One plus annual rate of change in state and local government wage and salary rate |
| $\mathrm{a}_{11}$ | Wage and salary rate of federal government employees |
| $\mathrm{a}_{12}$ | One plus annual rate of change in federal wage and salary rate |
| $\mathrm{a}_{13}$ | One plus annual rate of change in military payroll |
| $\mathrm{a}_{14}$ | One plus annual rate of change in transfer payments |
| $\mathrm{a}_{15}$ | One plus annual rate of change in property income |
| $\mathrm{a}_{16}$ | One plus annual rate of change in other labor income |
| $\mathrm{a}_{17}$ | Ratio of social security payments to wage and salary income |
| $\mathrm{a}_{18}$ | One plus annual rate of change in $\mathrm{a}_{17}$ |

Figure 2. Flow Chart of the Oklahoma Simulation Model
plant and equipment, (2) replacement investment, and (3) households' purchases of residential housing.

New plant and equipment, the first component of total investment, is estimated by using the acceleration principle. It is estimated by multiplying capital-output ratios, annual change in capital-output ratios, and the difference of sector outputs between year $t-1$ and $t-2$.

$$
\begin{equation*}
[\operatorname{In}]_{t}=\left[A_{1}\right]_{t-1} A_{2}\left[\left[x^{d}\right]_{t-1}-\left[x^{d}\right]_{t-2}\right] \tag{5.1}
\end{equation*}
$$

where

$$
\begin{aligned}
{[\mathrm{In}]_{t} } & =\underset{\text { year } t}{\text { column vector of new plant and equipment investment in }} \\
{\left[A_{1}\right]_{t-1}=} & \text { diagonal matrix of average capital-output ratios in } \\
& \text { year }
\end{aligned}
$$

$\mathrm{A}_{2}=\begin{aligned} & \text { diagonal matrix of one plus annual change in capital- } \\ & \text { output ratios }\end{aligned}$ $\left[x^{d}\right]_{t-1}=$ column vector of sector output in year $t-1$.

The diagonal matrix of $A_{2}$ reflects the technological change and incorporates this change into future estimates of capital as trends in the capital-output ratios.

Capital stock at the beginning of each period is equal to capital stock at the beginning of the preceding period plus new plant and equipment investment made during the preceding period.

$$
\begin{equation*}
[\mathrm{K}]_{\mathrm{t}}=[\mathrm{K}]_{\mathrm{t}-1}+[\mathrm{In}]_{\mathrm{t}-1} \tag{5.2}
\end{equation*}
$$

where
$[k]_{t}=$ column vector of capital stock at the beginning of year $t$
$[\mathrm{In}]_{\mathrm{t}-1}=\underset{\text { column vector of new plant and equipment investment made }}{ } \quad$ during year t .

Replacement investment, the second component of total investment, is obtained by multiplying sector capital stocks by respective depreciation rates.

$$
\begin{equation*}
[\mathrm{Ir}]_{t}=\mathrm{A}_{3}[\mathrm{~K}]_{t} \tag{5.3}
\end{equation*}
$$

where:
$[I r]_{t}=$ column vector of replacement investment in year $t$
$A_{3}=$ diagonal matrix of depreciation rates.
Households' expenditures, the third component of total investment, on residential housing is estimated as follows:

$$
\begin{equation*}
[\mathrm{Ih}]_{\mathrm{t}}=\mathrm{A}_{4}[\mathrm{Ih}]_{\mathrm{t}-1} \tag{5.4}
\end{equation*}
$$

where:
$[I h]_{t}=$ column vector of household expenditures on residential housing in year $t$
$A_{4}=$ diagonal matrix of one plus annual rate of change in households' residential housing expenditures.

Total investment $[I]_{t}$ is determined by adding the three components.

$$
\begin{equation*}
[I]_{t}=[I r]_{t}+[I n]_{t}+[I h]_{t} \tag{5.5}
\end{equation*}
$$

The composition of sectors' new investment is determined by multiplying the capital coefficient matrix times total investment.

$$
\begin{equation*}
[\mathrm{CA}]_{t}=\mathrm{A}_{5}[\mathrm{I}]_{t} \tag{5.6}
\end{equation*}
$$

where:
$[C A]_{t}=$ column vector of composition of new investment in year $t$ $A_{5}=$ capital coefficient matrix.
b. Household Demand. Household demand is estimated by a method which is similar to the one used by Ekholm [9]. For the computation, income elasticity of each sector is utilized. First, the lagged percentage change for the previous three years in disposable income is estimated. Second, weights $\left(a_{1}, a_{2}, a_{3}\right)$ for the last three years are used to measure the impact of disposable income on demand. Weights for the previous three years are estimated ${ }^{1}$ by utilizing the information in [2] and [12]. If $a_{1}>a_{2}>a_{3}$, this indicates that the more recent income has more impact over the lagged household income.

$$
\begin{align*}
(\mathrm{LDI})_{t}= & a_{1}\left((\mathrm{DI})_{t-1}-(\mathrm{DI})_{t-2}\right) / .5\left((\mathrm{DI})_{t-1}+(\mathrm{DI})_{t-2}\right) \\
& \left.a_{2}\left((\mathrm{DI})_{t-2}-(\mathrm{DI})_{t-3}\right) / .5\left((\mathrm{DI})_{t-2}\right)+(\mathrm{DI})_{t-3}\right) \\
& a_{3}\left((\mathrm{DI})_{t-3}-(\mathrm{DI})_{t-4}\right) / .5\left((\mathrm{DI})_{t-3}+(\mathrm{DI})_{t-4}\right) \tag{5.7}
\end{align*}
$$

where:
(LDI) $_{t}=$ lagged percentage change in disposable income for year $t$
(DI) t-1 $=$ disposable income in year $t-1$
$\begin{aligned} & a_{1}, a_{2}, a_{3}= \text { weights of percentage change in disposable income for } \\ & \text { the previous three years. }\end{aligned}$
Household demand is estimated by using three pieces of information:
(1) the previous year's household demand, (2) lagged percentage change in disposable income, and (3) each sector's income elasticity.

$$
\begin{equation*}
\left[c_{j}\right]_{t}=\left[c_{j}\right]_{t-1}+(L D I)_{t} A_{6}\left[c_{j}\right]_{t-1} \tag{5.8}
\end{equation*}
$$

where:
$1_{\text {The sum of the weights }}$ is forced to be equal to one in order to have the impact complete. The weights are estimated as: $a_{1}=605$, $a_{2}=272$, and $a_{3}=123$.
$\left[C_{j}\right]_{t}=\underset{\text { year } t}{\text { column vector of personal consumption demand by sector in }}$
$A_{6}=$ diagonal matrix of estimated income elasticities by sector.
Sectors' income elasticities are adopted from Mullendore and Ekholm [29].
c. Export Demand. States' export demand are influenced mainly by the United States' demand. Therefore, it is assumed that Ok1ahoma exports grow in the same proportions as the United States' demand and estimated from [56]. Demand for services sectors (sectors 4, 14, 15, 16, and 17) are assumed to be determined by state economic activity and are not related to the United States' demand. The total export demand is obtained by summing the two components which are export demand for durables and export demand for non-durables.

$$
\begin{align*}
& {[\mathrm{En}]_{t}=\mathrm{A}_{7}[\mathrm{En}]_{\mathrm{t}-1}}  \tag{5.9}\\
& {[\mathrm{Ed}]_{t}=\mathrm{A}_{8}[\mathrm{Ed}]_{\mathrm{t}-1}}  \tag{5.10}\\
& {[\mathrm{Et}]_{\mathrm{t}}=[\mathrm{En}]_{t}+[\mathrm{Ed}]_{t}} \tag{5.11}
\end{align*}
$$

where:
$[\mathrm{En}]_{t}=$ column vector of export demand for non-durables in year $t$
$A_{7}=$ diagonal matrix of one plus annual growth rate of non-durables
$[E d]_{t}=$ column vector of export demand for durables in year $t$
$A_{8}=$ diagonal matrix of one plus annual growth rate of durables
$[E t]_{t}=$ total export demand in year $t$.
d. Federal Government Purchases in Oklahoma. Federal government purchases in Oklahoma are estimated as a function of the previous year's
purchases. The column vector of federal government purchases in Oklahoma in year t-1 is multiplied by one plus the growth rate in federal government expenditures in Oklahoma ( $\mathrm{a}_{4}$ ). ${ }^{2}$

$$
\begin{equation*}
[\mathrm{TFE}]_{\mathrm{t}}=\mathrm{a}_{4}[\mathrm{TFE}]_{\mathrm{t}-1} \tag{5.12}
\end{equation*}
$$

where:
$[T F E]_{t}=\begin{aligned} & \text { column vector of total federal government purchases in } \\ & \text { Oklahoma in year } t\end{aligned}$
e. State and Local Government Purchases. State and local government expenditures on education, highways, public welfare, health and hospitals, and others are estimated individually. For each of these estimates, the lagged value of the independent variable is used. Here, it is implicitly assumed that changes in independent variables show their effect on dependent variables during the following year. Total personal income and personal income per capita are the variables most frequently used for state and local government expenditure estimates. For the first year estimates, these are fed into the model. For following years, the estimates are obtained within the model. Highway expenditures are projected as a function of gasoline tax collection of the preceding year. State and local government expenditure estimates are

[^4]given in five equations ${ }^{3}$ as follows:
\[

$$
\begin{align*}
& { }^{(\mathrm{EE})_{t}}=-\underset{(\mathrm{t}=13.023+.77)}{-113.08568(\mathrm{TPI})_{t-1} / 1000}  \tag{5.13}\\
& \mathrm{~s}^{2}=439.45 \quad \mathrm{~d}=1.520 \quad \hat{\rho}=.187 \quad \mathrm{R}^{2}=.9499 \\
& \text { (HE) }_{t}=-33.691+.000286(\mathrm{GT})_{t-1}  \tag{5.14}\\
& \mathrm{~s}^{2}=144.81 \quad \mathrm{~d}=1.353 \quad \hat{\rho}=.213 \quad \mathrm{R}^{2}=.5879 \\
& { }^{(P W)_{t}}=-40.180+.092316(P I P)_{t-1}  \tag{5.15}\\
& s^{2}=93.49 \quad \mathrm{~d}=1.744 \quad \hat{\rho}=.001 \quad \mathrm{R}^{2}=.9105 \\
& \begin{aligned}
&(\mathrm{HH})_{t}=-33.078+.01588(\mathrm{TPI})_{t-1} / 1000 \\
&(\mathrm{t}=9.20)
\end{aligned}  \tag{5.16}\\
& s^{2}=33.84 \quad \mathrm{~d}=1.047 \quad \hat{\rho}=.337 \quad \mathrm{R}^{2}=.8943 \\
& { }^{(\mathrm{OE})_{t}}=\underset{(\mathrm{t}=8.53)}{-100.669+.05489(\mathrm{TPI})_{t-1} / 1000}  \tag{5.17}\\
& s^{2}=469.77 \quad d=1.353 \quad \hat{\rho}=.214 \quad R^{2}=.8793
\end{align*}
$$
\]

where:
$(E E)_{t}=$ state and local government expenditures on education in Oklahoma in year $t$ ( $\$$ million)
(TPI) ${ }_{t-1}=$ total personal income in Oklahoma in year $\mathrm{t}-1$
$(\mathrm{HE})_{t}=$ state and local government expenditures on highways in Oklahoma in year $t$ ( $\$$ million)
$3^{\text {For estimating equations (5.13) through (5.17), it is assumed }}$ that the dependent variables do not influence the independent variables.
${ }^{(G T)}{ }_{t-1}=$ gasoline and fuels excise and special fuels use tax in Oklahoma in year t-1
$\left.{ }^{(P W)}\right)_{t}=$ state and local government expenditures on public welfare in year $t$ ( $\$$ million)
(PIP) $_{t-1}=$ personal income per capita in Oklahoma in year $t-1$
${ }^{(H H)}{ }_{t}=$ state and local government expenditures on health and hospitals in Oklahoma in year $t$ ( $\$$ million)
${ }^{(O E)_{t}}=$ other state and local government expenditures in Oklahoma in year $t$ ( $\$$ million).

Total state and local government expenditures in year $t(T S E)_{t}$ are found as follows:

$$
\begin{equation*}
(\mathrm{TSE})_{t}=\left({ }^{\left.(\mathrm{EE})_{t}+(\mathrm{HE})_{t}+(\mathrm{PW})_{t}+(\mathrm{HH})_{t}+(\mathrm{OE})_{t}\right) \cdot 1000}\right. \tag{5.18}
\end{equation*}
$$

By utilizing the column vector whose elements are proportions of total state and local government purchases by sector in Oklahoma, this total expenditure is distributed into sectors.

$$
\begin{equation*}
[T S E]_{t}=A_{9}(T S E)_{t} \tag{5.19}
\end{equation*}
$$

where:
$[T S E]_{t}=\begin{gathered}\text { column vector of total state and local government pur- } \\ \text { chases in Oklahoma in year } t\end{gathered}$ chases in Oklahoma in year $t$
$A_{9}=$ column vector whose elements are proportions of total state and local government purchases by sector in Oklahoma.
f. Total Final Demand. After estimating each sector in final demand, total final demand can be estimated. To do this, individual final demand sectors need to be totaled.

$$
\begin{equation*}
\left[z_{t}\right]=[\mathrm{CA}]_{t}+\left[\mathrm{C}_{\mathrm{j}}\right]_{\mathrm{t}}+[\mathrm{Et}]_{t}+[\mathrm{TFE}]_{t}+[\mathrm{TSE}]_{t} \tag{5.20}
\end{equation*}
$$

where:
$[\mathrm{z}]_{\mathrm{t}}=$ column vector of total final demand in Oklahoma in year t .

## 2. Determining Sector Output

Sector output estimates provide very important elements for employment projections. These estimates are obtained through multiplying the final demand estimates by the matrix of direct and indirect coefficients.

$$
\begin{equation*}
\left[\mathrm{x}^{\mathrm{d}}\right]_{\mathrm{t}}=\mathrm{A}_{10}[\mathrm{z}]_{\mathrm{t}} \tag{5.21}
\end{equation*}
$$

where:
$\left[x^{d}\right]_{t}=$ column vector of sector output estimates in year $t$
$\mathrm{A}_{10}=$ direct and indirect coefficient matrix.
Sector output estimates which are obtained in equation (5.21) can not be higher than the maximum sector output estimates which are obtained by considering labor and capital restrictions.

To estimate the maximum sector output due to labor restrictions, the first step is to determine the labor-output ratios. For the purpose of this study, labor-output coefficients are defined as the number of laborers required per thousand dollars of output in each sector. They are obtained by dividing each sector's employment by that sector's output and represent the average labor-output ratios. Sector employment is obtained by adding every element of occupation-component matrix of each sector. This is done for every sector and entered in a column vector. Sector employment estimation is given in equation (5.22).

$$
\left[L^{e}\right]_{t-1}=\sum_{k} \sum_{i}\left[\mathrm{OCM}_{j}\right]_{t-1} \quad \begin{align*}
& i=1,2, \ldots, 29  \tag{5.22}\\
& k=1,2 \\
& j=1,2, \ldots, 17
\end{align*}
$$

where:
$\left[L^{e}\right]_{t-1}=$ column vector of employment in Oklahoma in year $t-1$ $\left[0 C M_{j}\right]_{t-1}=$ occupation component matrix for $j^{\text {th }}$ sector in year $t-1$ $i=$ number of occupation groups in each $\left[\mathrm{OCM}_{\mathrm{j}}\right]$ matrix $k=$ number of component groups in each $\left[0 C M_{j}\right]$ matrix $j=$ number of $\left[\mathrm{OCM}_{\mathrm{j}}\right]$ matrices (one for each endogenous sector). The labor stock matrix (Table XV) may be derived from these 17 occupation-component matrices. First component of each matrix presents wage and salary employment of that sector by 29 occupation groups, whereas the second component presents proprietors by the same occupation groups. To obtain labor stock matrix, the second component needs to be totaled and entered as total proprietor employment. Wage and salary employment by occupation is the same in labor stock matrix and occupation-component matrix.

By using the sector employment column vector and the column vector of sector outputs which is obtained in equation (5.21), it is possible to estimate the labor-output coefficients. Labor-output coefficients [LO] are obtained by dividing every entry in sector employment column vector by corresponding element in sector output column vector as it is given in equation (5.23).

$$
\begin{equation*}
[\mathrm{LO}]_{\mathrm{t}-1}=\left[\mathrm{L}^{\mathrm{e}}\right]_{\mathrm{t}-1} /\left[\mathrm{x}^{\mathrm{d}}\right]_{\mathrm{t}-1} \tag{5.23}
\end{equation*}
$$

The second step in determining the maximum sector output due to labor restrictions is to estimate the amount of available labor for each sector. Available labor by sector is estimated by utilizing the three pieces of information: (1) labor force-employment ratio, (2) one plus annual growth rate of employment, and (3) sector employment in year
t-1. It is given as follows:

$$
\begin{equation*}
[\mathrm{L}]_{\mathrm{t}}=\mathrm{A}_{11} \mathrm{~A}_{12}\left[\mathrm{~L}^{\mathrm{e}}\right]_{\mathrm{t}-1} \tag{5.24}
\end{equation*}
$$

where:
$[L]_{t}=$ column vector of available labor by sector in year $t$
$\mathrm{A}_{11}=$ diagonal matrix of labor force-employment ratio
$A_{12}=$ diagonal matrix of one plus growth rate of employment. The diagonal matrix of labor force-employment ratio is obtained by estimating the capacity employment and adjusting this downward by sector.

The maximum sector output due to labor restriction can be computed as follows:

$$
\begin{equation*}
\left[\mathrm{x}^{\mathrm{L}}\right]_{\mathrm{t}}=\left[\mathrm{A}_{13}\right]_{\mathrm{t}-1} \mathrm{~A}_{14}[\mathrm{~L}]_{\mathrm{t}} \tag{5.25}
\end{equation*}
$$

where:
$\left[X^{L}\right]_{t}=$ maximum sector output due to labor restriction in year $t$
$\left[A_{13}\right]_{t-1}=$ diagonal matrix where each element is reciprocal of corresponding labor-output coefficient in year t-1
$\left[A_{14}\right]=$ diagonal matrix of one plus annual rate of change in $\left[A_{13}\right]_{t-1}$.

The maximum output due to capital restriction is computed by four pieces of information that are already available and is given in equation (5.26).

$$
\begin{equation*}
\left[\mathrm{x}^{\mathrm{c}}\right]_{\mathrm{t}}=\left[\mathrm{x}^{\mathrm{c}}\right]_{\mathrm{t}-1}+[\mathrm{In}]_{\mathrm{t}} /\left[\mathrm{A}_{15}\right]_{\mathrm{t}-1} \mathrm{~A}_{2} \tag{5.26}
\end{equation*}
$$

where:
$\left[X^{c}\right]_{t}=$ maximum sector output due to capital restriction in year $t$

$$
[\mathrm{In}]_{t}=\underset{\text { year } t}{\text { column vector of new plant and equipment investment in }}
$$

$\left[A_{15}\right]_{t-1}=\begin{aligned} & \text { diagonal matrix of capital output ratios defined at } \\ & \text { capacity levels in year } t-1\end{aligned}$
$A_{2}=$ diagonal matrix of one plus annual change in capitaloutput ratios.

## 3. Relationships Projecting State Economic

## Variables

After estimating output, variables such as employment, population, income, value added, federal government and state and local government revenues, personal income, and disposable income can be projected.
a. Employment. Two different procedures are followed to estimate employment for the endogenous sectors and the exogenous sectors. Employment projections are made in this order, and then they are combined to project the total employment in Oklahoma.
(1) Employment Projections for Endogenous Sectors. Sector employment projections are obtained as products of three pieces of information: (1) sector output, (2) labor-output coefficient, and (3) one plus annual rate of change in labor-output coefficient and are given in equation (5.27).

$$
\begin{equation*}
\left[\mathrm{L}^{\mathrm{e}}\right]_{\mathrm{t}}=\mathrm{A}_{16}\left[\mathrm{~A}_{17}\right]_{\mathrm{t}}[\mathrm{LO}]_{\mathrm{t}-1} \tag{5.27}
\end{equation*}
$$

where:
$\left[L^{e}\right]_{t}=$ column vector of sector employment in year $t$
$A_{16}=\begin{aligned} & \text { diagonal matrix } \\ & \text { coefficient }\end{aligned}$
$\left[\mathrm{A}_{17}\right]_{\mathrm{t}}=$ diagonal matrix where elements are representing the corresponding elements of column vector of sector output
$[\mathrm{LO}]_{t-1}=\underset{\text { year } t-1}{\text { column vector }}$ of 1 abor-output coefficients by sector in year $t-1$.

Total employment in endogenous sectors (E) ${ }_{t}$ is obtained by totaling all of the entries of column vector of sector employment as follows:

$$
\begin{equation*}
(E)_{t}=\sum_{j}[L]_{t} \tag{5.28}
\end{equation*}
$$

Sector employment estimates, base year's sector employment, and base year's occupation-component matrices are utilized to project the employment in the form of occupation-component matrices by sector. Equation (5.29) displays this computation procedure.

$$
\begin{equation*}
\left[O C M_{j}\right]_{t}=\left[O C M_{j}\right]_{t-1}\left(\left(L_{j}^{e}\right)_{t} /\left(L_{j}^{e}\right)_{t-1}\right) \tag{5.29}
\end{equation*}
$$

where:
$\left[O C M_{j}\right]_{t}=$ occupation component matrices by sector in year $t$
$\left(L_{j}^{e}\right)_{t}=j_{\text {the column vector of }[L}^{\text {th }}$ sector's total employment in year $t$ (or $j^{\text {th }}$ element in
(2) Manpower Analysis. Manpower analysis of the Oklahoma model is based on 17 matrices which are obtained in equation (5.29) above. By using these matrices and the similar matrices of the base year, it is possible to project the labor needs by occupation and component for each endogenous sector. It is also possible to project the total labor needs for the endogenous sectors of Oklahoma model by occupation and component. The manpower analysis is constructed around the following seven equations.

The first of these seven equations projects the labor needs for the endogenous sectors of this model, and is obtained by subtracting base year's occupation-component matrix from the projected occupationcomponent matrix for each sector.

$$
\begin{equation*}
\left[\mathrm{OCM}_{j}\right]_{\mathrm{t}-1}^{\mathrm{t}}=\left[\mathrm{OCM}_{j}\right]_{t}-\left[\mathrm{OCM}_{j}\right]_{\mathrm{t}-1} \tag{5.30}
\end{equation*}
$$

where:
$\left[\mathrm{OCM}_{\mathrm{j}}\right]_{\mathrm{t}-1}^{\mathrm{t}}=\begin{aligned} & \text { occupation-component matrix for } \\ & \\ & \text { sector from year } t-1 \text { to year } t .\end{aligned}$
The matrices which are projected in equation (5.30) are simply representing the additional demand for labor in each sector. Positive values in each matrix imply an expansion of employment in that sector, whereas negative values indicate a contraction.

By adding all of these 17 matrices together, the occupationcomponent matrix for needed labor in Oklahoma from year $\mathrm{t}-1$ to year t can be obtained and is given as follows:

$$
\begin{equation*}
[\mathrm{OCM}]_{\mathrm{t}-1}^{\mathrm{t}}=\sum_{\mathrm{j}}\left[\mathrm{OCM}_{\mathrm{j}}\right]_{\mathrm{t}-1}^{\mathrm{t}} \tag{5.31}
\end{equation*}
$$

The same matrix may be obtained by following a different procedure. In this method, first, occupation component of employment matrices for needed labor in Oklahoma in year $\mathrm{t}-1$ and in year t are obtained. By subtracting the previous matrix from the latter, the same matrix as in equation (5.31) can be obtained. Computations are given in equations (5.32), (5.33), and (5.34).

$$
\begin{align*}
& {[O C M]_{t-1}=\sum_{j}\left[O C M_{j}\right]_{t-1}}  \tag{5.32}\\
& {[O C M]_{t}=\sum_{j}\left[O C M_{j}\right]_{t}}  \tag{5.33}\\
& {[O C M]_{t-1}^{t}=[O C M]_{t}-[O C M]_{t-1}} \tag{5.34}
\end{align*}
$$

where:
$\left[\mathrm{OCM}_{t}\right]=\begin{aligned} & \text { occupation component matrix for the endogenous sectors of } \\ & \\ & \text { Oklahoma in year } t .\end{aligned}$

The last two equations of the manpower analysis project the employment of each sector by their components--wage and salary and pro-prietor--and the total wage and salary and the total proprietorship employment in Oklahoma. The first equation (5.35) represents a matrix which is obtained by adding the columns of each $\left[\mathrm{OCM}_{j}\right]_{t}$ and entering as corresponding rows of a 17 by 2 matrix. The second equation (5.36) represents a row vector whose elements are obtained by summing the entries of each column of the matrix which is obtained in equation (5.35). These two equations are given as follows:

$$
\begin{align*}
& {\left[\mathrm{L}_{\mathrm{L}} \mathrm{P}\right]_{t}=\sum_{i}\left[\mathrm{OCM}_{\mathrm{j}}\right]_{t} \quad i=1,2, \ldots, 29 .}  \tag{5.35}\\
& {\left[\mathrm{L}_{\mathrm{w}} \mathrm{~L}_{\mathrm{p}}\right]_{\mathrm{t}}=\sum_{j}\left[\mathrm{~L}^{W_{L} \mathrm{P}}\right]_{t}} \tag{5.36}
\end{align*}
$$

where:
$\left[L^{W} L^{p}\right]_{t}=$ matrix of wage and salary and proprietor employment by sector for the endogenous sectors of Oklahoma in year $t$
$\left[L_{w} L_{p}\right]_{t}=$ row vector of total wage and salary and proprietor employment of the endogenous sectors of Oklahoma in year t.
(3) Employment Projections for Government Sectors. Projections of federal government and state and local government employment are obtained as follows:

$$
\begin{align*}
& {\left[L_{f}\right]_{t}=a_{5}\left[L_{f}\right]_{t-1}}  \tag{5.37}\\
& {\left[L_{s}\right]_{t}=a_{6}\left[L_{s}\right]_{t-1}} \tag{5.38}
\end{align*}
$$

where:

$$
\begin{aligned}
{\left[L_{f}\right]_{t}=} & \text { column vector of federal government employment by occupa- } \\
& \text { tion in Oklahoma in year } t
\end{aligned}
$$

$a_{5}=$ one plus annual rate of change in federal government employment
$\left[L_{s}\right]_{t}=$ column vector of state and local government employment by occupation in Oklahoma in year $t$
$a_{6}=$ one plus annual rate of change in state and local government employment.
(4) Total Oklahoma Employment. Total wage and salary employment in Oklahoma can be presented by occupation. To obtain this equation (5.33), (5.37), and (5.38) need to be utilized as in equation (5.39).

$$
\begin{equation*}
[\mathrm{WSE}]_{t}=[\text { OCM1 }]_{t}+\left[\mathrm{L}_{\mathrm{f}}\right]_{t}+\left[\mathrm{L}_{\mathrm{s}}\right]_{\mathrm{t}} \tag{5.39}
\end{equation*}
$$

where:

$$
\left.\begin{array}{rl}
{[\text { WSE }]_{t}=} & \text { total wage and salary employment by occupation in Okla- } \\
& \text { homa by year } t
\end{array}\right] \begin{aligned}
{[0 C M 1]_{t}=} & \text { column vector of wage and salary employment by occupa- } \\
& \text { tion for the endogenous sectors of Oklahoma in year } t
\end{aligned}
$$

Total employment may be obtained by summing the two components-namely, wage and salary employment and proprietor employment as given in equation (5.40).

$$
\begin{equation*}
(T E)_{t}=\sum_{i}[W S E]+\left(L_{p}\right)_{t} \tag{5.40}
\end{equation*}
$$

where:
$(\mathrm{TE})_{t}=$ total Oklahoma employment in year $t$
$\begin{aligned}\left(L_{p}\right)_{t}= & \text { total proprietor employment in Oklahoma in year } t \text { (second } \\ & \left.\text { element of }\left[L_{w} L_{p}\right]_{t}\right) .\end{aligned}$
b. Population. In this analysis, population is treated as an endogenous variable and projected within the model. Populationemployment ratio in year $t-1\left(a_{7}\right)_{t-1}$, total Oklahoma employment in
year $t$, and one plus annual rate of change in the populationemployment ratio ( $\mathrm{a}_{8}$ ) are the variables utilized for this purpose. The projection of population is given in equation (5.41) as follows:

$$
\begin{equation*}
(\mathrm{P})_{t}=\left(\mathrm{a}_{7}\right)_{t-1} \mathrm{a}_{8}(\mathrm{TE})_{t} / 1000 \tag{5.41}
\end{equation*}
$$

where:
$(P)_{t}=$ total Oklahoma population in year $t(000)$. The population employment ratio for the base year is computed by dividing the total Oklahoma population by the total employment in Oklahoma. For later years, this coefficient is estimated within the model by using the projections of employment and population which are obtained through the equations (5.40) and (5.41).
c. Income. In this section, wage and salary payments and proprietor income are projected by sector. Also, total value of all government wages and salaries, transfer payments, property income, and other labor income are estimated. With these estimates, it is possible to compute the total personal income and, thus, personal income per capita.

Wage and salary payments for the endogenous sectors are estimated by wage and salary employment, wage and salary income rates (or wage and salary rates), and the coefficients which reflect the annual change in the wage and salary rates. The procedure is given in equation (5.42).

$$
\begin{equation*}
\left[\mathrm{ws}_{\mathrm{t}}\right]=\left[\mathrm{A}_{18}\right]_{\mathrm{t}-1} \mathrm{~A}_{19}\left[\mathrm{~L}^{\mathrm{W}}\right]_{\mathrm{t}} / 1000 \tag{5.42}
\end{equation*}
$$

where:
$[W S]_{t}=$ wage and salary payments by sector in year $t$
$\left[\mathrm{A}_{18}\right]_{\mathrm{t}-1}=\underset{\text { year } \mathrm{t}-1}{ }(\$) \mathrm{matrix}$ of wage and salary rates by sector in
$\mathrm{A}_{19}=$ diagonal matrix of one plus annual growth rate of wages and salaries by sector
$\left[\mathrm{L}^{\mathrm{w}}\right]_{t}=\underset{\text { year } t}{ } \quad$ column vector of wage and salary employment by sector in
To estimate proprietor income, a procedure which is similar to wage and salary income projections is followed. Equation (5.43) displays this computation.

$$
\begin{equation*}
\left[\mathrm{Y}^{\mathrm{P}}\right]_{\mathrm{t}}=\mathrm{A}_{20 \mathrm{t}-1} \mathrm{~A}_{21}\left[\mathrm{~L}^{\mathrm{p}}\right]_{\mathrm{t}} / 1000 \tag{5.43}
\end{equation*}
$$

where:
$\left[\mathrm{Y}^{\mathrm{P}}\right]_{\mathrm{t}}=$ column vector of proprietor income by sector in year t $\left[A_{20}\right]_{t-1}=\underset{\text { in year } t-1(\$)}{ } \quad$ of proprietor income rate by sector
$A_{21}=\underset{\text { diagonal matrix of one plus annual rate of change in pro- }}{\text { priene }}$
$\left[L^{p}\right]_{t}=$ column vector of proprietor employment in year $t$.
Governmental wage and salary payments are projected by three components: federal government civilian, federal government military, and state and local government, and are given in equation (5.44).

$$
\begin{align*}
(F S)_{t}= & \left(\left(a_{9}\right)_{t-1} a_{10}\left(L_{s}\right)_{t}+\left(a_{11}\right)_{t-1} a_{12}\left(L_{f}\right)_{t}+a_{13}\right. \\
& \left.(A F)_{t-1}\right) / 1000 \tag{5.44}
\end{align*}
$$

where:
(FS) $_{t}=$ all governmental wages and salaries in year $t$
$\left(a_{9}\right)_{t-1}=\underset{\text { wage and salary rate of state and local government }}{\text { empear } t-1(\$)}$
$a_{10}=$ one plus annual rate of change in state and local government wage and salary rate
$\begin{aligned}\left(a_{11}\right)_{t-1}= & \text { wage and salary rate of federal government employees } \\ & \text { in year } t-1(\$)\end{aligned}$
$a_{12}=$ one plus annual rate of change in federal wage and salary rate
$a_{13}=$ one plus annual rate of change in military payroll
$\left(\mathrm{AF}_{\mathrm{t}-1}=\right.$ military payroll in Oklahoma in year $\mathrm{t}-1$ (\$).
Transfer payments, property income, and other labor income are all projected as a function of the previous year's amounts. These computations are given in the following three equations:

$$
\begin{align*}
& \left(\mathrm{Y}^{\mathrm{T}}\right)_{t}=a_{14}\left(\mathrm{Y}^{\mathrm{T}}\right)_{\mathrm{t}-1}  \tag{5.45}\\
& \left(\mathrm{Y}^{\mathrm{Py}}\right)_{t}=\mathrm{a}_{15}\left(\mathrm{Y}^{\mathrm{Py}}\right)_{\mathrm{t}-1}  \tag{5.46}\\
& (\mathrm{OY})_{t}=a_{16}(\mathrm{OY})_{\mathrm{t}-1} \tag{5.47}
\end{align*}
$$

where:
$\left(Y^{T}\right)_{t}=$ total transfer payments in Oklahoma in year $t$
$a_{14}=$ one plus annual rate of change in transfer payments
$\left(\mathrm{Y}^{\mathrm{Py}}\right)_{\mathrm{t}}=$ total property income in Oklahoma in year t
$a_{15}=$ one plus annual rate of change in property income
$\left.{ }^{(O Y}\right)_{t}=$ total other labor income in Oklahoma in year $t$
$a_{16}=$ one plus annual rate of change in other labor income.
After completing the projections of all of the income components, the total personal income in Oklahoma can be estimated. For this, the individual components are summed and social security payments of wage and salary employees are subtracted from that total, as given in
equation (5.48).

$$
\begin{align*}
(T P I)_{t}= & \left.\sum_{j}[W S]_{t}+\sum_{j}\left[Y^{P}\right]+(F S)_{t}+\left(Y^{T}\right)_{t}+Y^{P y}\right)_{t}+ \\
& (O Y)_{t}-a_{17} a_{18} \underset{j}{\left(\sum(W S)+(F S)_{t}\right)} \tag{5.48}
\end{align*}
$$

where:
$(T P I)_{t}=$ total personal income in Oklahoma in year $t$
$\mathrm{a}_{17}=$ ratio of social security payments to wage and salary income
a 18 one plus annual rate of change in $a_{17}$.
Dividing total personal income by Oklahoma population in year $t$ yields personal income per capita projections as follows:

$$
\begin{equation*}
(P I P)_{t}=(T P I)_{t} /(P)_{t} \tag{5.49}
\end{equation*}
$$

where:
$\left(\right.$ PIP $_{t}=$ personal income per capita in Oklahoma in year $t(\$)$
$(P)_{t}=$ Oklahoma population in year $t(000)$.
d. Value Added and Gross State Product. Value added by sector is estimated by using the estimate of sector output and the ratio of value added to output and is given in equation (5.50).

$$
\begin{equation*}
\left[\eta_{t}=A_{22}\left[x^{d}\right]_{t}\right. \tag{5.50}
\end{equation*}
$$

where:
$[\mathrm{v}]_{\mathrm{t}}=$ value added by sector in Oklahoma in year t
$A_{22}=$ diagonal matrix of the ratio of value added to output.
Gross state product $\left(\mathrm{X}^{\mathrm{g}}\right)$ is the sum of value added and all government wages and salaries.

$$
\begin{equation*}
\left(X^{g}\right)_{t}=\sum_{j} \quad v_{t}+(F S)_{t} \tag{5.51}
\end{equation*}
$$

e. Federal Government Revenues. Federal revenues consist of federal government tax collections in Oklahoma. These revenues are estimated in a simple regression equation which is given as follows:

$$
\begin{align*}
&(T F R)_{t}=60476.909+190.01079(T P I)_{t} / 1000  \tag{5.52}\\
&(t=9.67)
\end{align*} s^{2}=4801050570 \quad \mathrm{~d}=1.618 \quad \hat{\rho}=.177 \quad R^{2}=.9033 .
$$

where:
$(T F R)_{t}=$ federal government tax collections in Oklahoma in year $t$
$(T P I)_{t}=$ total personal income in Oklahoma in year $t$.
Individual income tax which is included in total federal tax revenues is estimated separately so that estimation of disposable income can be possible. Individual income tax is projected in a simple regression whose independent variable is total employment.

$$
\begin{align*}
(\mathrm{IIT})_{t} & =-2226558.032+\underset{(\mathrm{t}=10.02)}{3240.11673(\mathrm{TE})_{\mathrm{t}} / 1000}  \tag{5.53}\\
\mathrm{~s}^{2} & =3001074918 \quad \mathrm{~d}=1.493 \quad \hat{\rho}=.247 \quad \mathrm{R}^{2}=.9094
\end{align*}
$$

where:
$(\text { IIT })_{t}=\underset{\text { year } t}{ } \quad$ federal individual income tax collections in Oklahoma in
$(\mathrm{TE})_{t}=$ total Oklahoma employment in year $t$.
f. State and Local Government Revenues. State and local government revenues are considered in six components, and each component is estimated in a simple regression equation. The six components of state and local government revenues include (1) state sales tax, (2) gasoline
and fuels excise and special fuels use tax, (3) state collections of individual and corporation income tax, (4) other state and local government taxes, (5) federal aid to state and local governments, and (6) all other revenues of state and local governments. These six simple regression equations are given in equations (5.54) through (5.59), as follows:

$$
\begin{align*}
& (\mathrm{ST})_{t}=32865.220+\underset{(\mathrm{t}=11.06)}{6.02022(\mathrm{TPI})_{t}} / 1000  \tag{5.54}\\
& s^{2}=3680915 \quad d=1.289 \quad \hat{\rho}=.139 \quad R^{2}=.9244 \\
& (\mathrm{GT})_{t}=47133.166+\underset{(\mathrm{t}=5.21)}{10.64550(\mathrm{PIP})_{t}}  \tag{5.55}\\
& \mathrm{~s}^{2}=4891574 \quad \mathrm{~d}=1.101 \quad \hat{\rho}=.140 \quad \mathrm{R}^{2}=.7311 \\
& (\mathrm{IT})_{t}=-43071.533+\underset{(\mathrm{t}=6.34)^{16.57910(P I P)_{t}}}{t}  \tag{5.56}\\
& s^{2}=85056437 \quad \mathrm{~d}=1.517 \quad \hat{\rho}=-.084 \quad \mathrm{R}^{2}=.8006 \\
& \begin{aligned}
&(\mathrm{OT})_{t}=-19619.533+ 73.98709(\mathrm{PIP})_{t} \\
&(\mathrm{t}=8.42)
\end{aligned}  \tag{5.57}\\
& \mathrm{s}^{2}=90524959 \quad \mathrm{~d}=1.327 \quad \hat{\rho}=.032 \quad \mathrm{R}^{2}=.8765 \\
& \text { (FA) }_{t}=-208324.648+\underset{(\mathrm{t}=13.24)}{187.18952(P I P)_{t-1}}  \tag{5.58}\\
& s^{2}=222971116 \quad d=1.869 \quad \hat{\rho}=.002 \quad R^{2}=.9460 \\
& \mathrm{OR}_{\mathrm{t}}=-258787.748+\underset{(\mathrm{t}=21.96)}{183.03666(\mathrm{PIP})_{t}}  \tag{5.59}\\
& s^{2}=81526609 \quad d=1.349 \quad \hat{\rho}=.290 \quad R^{2}=.9797
\end{align*}
$$

where:
$(\mathrm{ST})_{t}=\operatorname{yetal}_{\text {year } t} \mathrm{value}$ of state sales tax collections in Oklahoma in
$(G T)_{t}=$ gasoline and fuels excise and special fuels use tax collections in Oklahoma in year $t$
$(I T)_{t}=$ individual and corporation income tax withheld by the State in Oklahoma in year $t$
$\begin{aligned}(O T)_{t}= & \text { all other taxes collected by state and local government in } \\ & \text { Oklahoma in year } t\end{aligned}$
$(F A)_{t}=\underset{\text { year } t}{\text { federal aid to state and local government in Oklahoma in }}$
$(O R)_{t}=$ other revenues to state and local government in Oklahoma in year $t$.

Projections of total state and local government revenues (TSR) $t$ are obtained by adding the six components and is given in equation (5.60).

$$
\begin{equation*}
(\mathrm{TSR})_{t}=(\mathrm{ST})_{t}+(\mathrm{GT})_{t}+(\mathrm{IT})_{t}+(\mathrm{OT})_{t}+(\mathrm{FA})_{t}+(\mathrm{OR})_{t} \tag{5.60}
\end{equation*}
$$

g. Disposable Income. Disposable income is obtained by subtracting federal individual income tax and state and local individual and corporation income tax collections from total personal income as in equation (5.61).

$$
\begin{equation*}
(D I)_{t}=(T P I)_{t}-(I I T)_{t}-(I T)_{t} \tag{5.61}
\end{equation*}
$$

where:
$(\mathrm{DI})_{t}=$ disposable income in Oklahoma in year $t$
$(\operatorname{IIT})_{t}=\begin{aligned} & \text { federal individual income tax collections in } 0 k l a h o m a \\ & \\ & \text { in year }\end{aligned}$
$(\mathrm{IT})_{t}=$ individual and corporation income tax withheld by the State in Oklahoma in year $t$.

Disposable income per capita is projected by merely dividing the disposable income which is obtained in equation (5.61) by Oklahoma
population which is projected in equation (5.41) of the same year.

$$
\begin{equation*}
(D I P)_{t}=(D I)_{t} /(P)_{t} \tag{5.62}
\end{equation*}
$$

where:
$(\text { DIP })_{t}=$ disposable income per capita in Oklahoma in year $t(\$)$
$(\mathrm{P})_{t}=$ total Oklahoma population in year $\mathrm{t}(000)$.

## CHAPTER VI

SIMULATION OF STATE ECONOMIC VARIABLES

Using the data presented in the Oklahoma social accounts from Chapters III, IV, and Appendix A, the Oklahoma Model presented in Chapter V simulates the Oklahoma economy from 1967 through 1985. Data which are not presented in the accounts are presented in Appendix C. The simulation period could be expanded to cover more years. However, the longer the period, the less reliable the projections due to the assumptions of the model. Simulating the variables from 1967 through 1985 is a short enough time period to rely on projections, but also long enough to be useful for planning purposes. This chapter presents and discusses simulation results of state economic variables from 1967 through 1985. Projections include employment, population, income, government revenues, government expenditures, and gross state product. Also, projections and discussions of manpower needs of Oklahoma are presented. The projected values are compared with the published data to measure the closeness of fit provided by the simulation model.

## A. Employment Projections

Employment projections are presented in Figures 3, 4, 5, and Table XXVIII. Figure 3 contains the estimates of total employment, wage and salary employment and proprietor employment. Estimated figures are indicated with solid lines, whereas published data are shown with broken

Figure 3. Total Employment, Wage and Salary Employment, and Proprietor Employment Projections, Oklahoma
lines. Published data are obtained from Oklahoma Employment Security Commission [34] and Oklahoma Department of Agriculture [32]. Total employment which is 944,100 in 1967 is forecast to be $1,447,917$ in 1985. Projected wage and salary employment is estimated in 1985 to be $1,140,230$, compared to 725,300 in 1967 , while proprietor employment is estimated at 307,687 in 1985 compared to 218,800 in 1967. The increase in wage and salary employment is more significant than the increase in proprietor employment. Part of this is explained by the agricultural sector. Proprietor employment in the agricultural sector is decreasing and offsetting the increase in proprietor employment of the other sectors. Starting from 1970, the definition of agricultural proprietor employment was changed. The change resulted in proprietor employment being about 50,000 less than it was in 1969. The effect of the change is seen in total employment, as well. However, parallel lines of published and projected values indicate the closeness of the fit in general.

Figure 4 contains projections for the number of wage and salary workers and proprietors for agriculture derived from the simulation model. Total employment in agriculture is expected to decline from 120,800 in 1967 to 97,281 in 1985. The number of proprietors is expected to decline from 101,800 in 1967 to 81,979 in 1985, and the wage and salary employment from 19,000 in 1967 to 15,302 in 1985. Projected figures for agricultural sector employment are obtained from Oklahoma Employment Security Commission [33] and Oklahoma Department of Agriculture publications [32].

Figure 5 contains projections of wage and salary employees in mining, manufacturing, and services sectors. Mining sector employment is the only other sector (other than agriculture) where employment is

expected to decline. Wage and salary employment in the mining sector is expected to decline from 41,000 in 1967 to 30,212 in 1985. Employment in manufacturing and services sector are expected to rise. Wage and salary employment in services sectors (sectors $4,14,15,16$, and 17) is expected to increase from 372,500 in 1967 to 685,588 in 1985. Wage and salary employment in manufacturing sectors (sectors 8 through 13) is expected to increase from 116,400 in 1967 to 178,955 in 1985. Projected employment figures are very similar in all cases to the published data, which are obtained from Oklahoma Employment Security Commission publications [34].

Table XXVIII contains detailed wage and salary employment projections for each endogenous sector, proprietor employment projections and government employment projections from 1967 through 1985. Published figures obtained from Oklahoma Employment Security Commission publications are included in this table. For instance, wage and salary employment in the other manufacturing sector is expected to increase from 19,900 in 1967, to 25,812 in 1985. Published wage and salary employment figures in this sector are very similar to the projected figures.

## B. Manpower Analysis

Persistent high levels of unemployment have focused attention on manpower problems. High levels of unemployment may result from (1) a deficiency of aggregate demand, or (2) from structural maladjustments in the manpower market. Structural maladjustments generally arise from changing technological patterns and shifts in the pattern of economic growth. Problems of structural adjustment can be satisfactorily

## TABLE XXVIII

WAGE AND SALARY EMPLOYMENT, PROPRIETOR EMPLOYMENT AND TOTAL EMPLOYMENT PROJECTIONS, OKLAHOMA, 1967-1985

brubishad rigree.
managed if a sufficiently high level of aggregate demand is maintained. Thus, an initial concern in manpower analysis and planning is to relate manpower requirements by occupation and level of education accurately to anticipated levels of aggregated demand.

The need for manpower analysis is evident from the preceding paragraph. In this section, the labor structure of the State is analyzed. Relationships between labor requirements and anticipated levels of aggregated demand are specified in the simulation model. Once these relationships are specified, the model can be used (1) to project future manpower needs for the state, or (2) to measure manpower needs for alternative development strategies. State leaders, planners and educators need to know future manpower needs if an adequate supply of labor by occupation will be available. Likewise, if state or local leaders are encouraging a change in the economic structure, such as location of a large army plant, it will be useful to know the types of jobs created by occupation. Then, state and local leaders can evaluate whether or not the region has an adequate supply of labor by occupation and skill level.

Employment data are given by industrial groupinge for 440 occupations [35]. For this study, the industrial groupings were aggregated to match the sectors in the Oklahoma model. In addition, the 440 occupations were aggregated to 29 occupational groups. ${ }^{1}$ Occupations requiring somewhat similar skills were grouped together, making the data easier to work with and present.

[^5]The aggregation process creates a limitation on the study. Individual occupations cannot be analyzed. However, the aggregation was performed such that occupations with similar skills were groupted together. Thus, the limitation for projection purposes is not quite so crucial. Another limitation arises because substitution does exist between some occupations. Unskilled workers may switch among occupation groups which do not require specific skills.

The Oklahoma Simulation Model projects manpower needs for Oklahoma from 1967 through 1985. Manpower needs of Oklahoma by occupation from 1967 through 1985 are presented in Table XXIX. This table is obtained by adding the number of employees in each occupation group for each sector for each year from 1967 through 1985. For instance, the projected number of wage and salary employees in Oklahoma is 13,513 engineers (occupation group 1); 3,483 scientists (occupation group 2); 27,170 technicians (occupation group 3); etc. Total number of wage and salary employees is $1,140,230$; total number of proprietors is 307,687; and total employment is $1,447,917$ in Oklahoma in 1985.

Only the total Oklahoma employment by occupation table is presented in Table XXIX. Similar tables-one for each endogenous sector, federal government sector, and state and local government sector--are presented in Appendix D.

Change in total Oklahoma employment by occupation for 1970, 1975, 1980, and 1985 are presented in Table XXX. Each entry is obtained by subtracting the number of employees in each occupation in 1967 from the number of employees in each occupation of the corresponding year in Table XXIX. Each entry indicates the demand for the employment of each occupation group in the corresponding year. For instance, the demand

|  | Total wage and salary | 59,864 | 149,664 | 257,224 | 414,930 |
|  | Total proprietorship | 11,334 | 27,198 | 50,545 | 88,887 |
|  | Total employment | 71,198 | 176,862 | 307,769 | 503,817 |

for engineers (occupation group 1) are expected to be 2,618 more than the actual number employed in 1967. The greatest demand for employment is expected to occur in other clerical workers (occupation group 13), for 51,177 more employees are projected for 1985. It is followed by miscellaneous operatives (occupation group 24) by 47,772 , sales workers (occupation group 10) by 37,075 , other managers and administrators (occupation group 9) by 32,221 , and personnel service workers (occupation group 27) by 27,885. Employment in each occupation group is expected to increase from 1967 to 1970 , 1975, 1980, and 1985 except scientists (occupation group 2). The demand for scientists is projected to be less in 1970 and 1975 than the number of scientists hired in 1967. However, more scientists are expected to be demanded by 1980 and 1985. The demand for wage and salary employees is expected to be 414,930 more than it was in 1967. Also, 88,887 more proprietors are expected to be demanded by 1985 compared to 1967. The total employment is expected to increase by 503,817 in 1985 over the total employment in 1967.

## C. Population Projections

Data in Figure 6 contains estimates of Oklahoma population from 1967 through 1985. Oklahoma population is expected to increase from 2,489,000 in 1967 to $2,962,000$ in 1985. Figure 6 also contains the published population data which are obtained from Oklahoma Employment Security Commission publications and Oklahoma Employment Security Commission projections of Oklahoma population for 1975, 1980, and 1985. Projected and published population figures are close until 1974, where the difference between the two figures is about 65,000.

## D. Income Projections

Table XXXI presents estimates of total personal income, wage and salary payments, other labor income, proprietor income, property income, and transfer payments from 1967 through 1985. Published data which are obtained from the U. S. Department of Commerce, Bureau of the Census publications $[78],[79],[80]$, and $[81]$ are also included in the table. Total personal income is expected to increase from $\$ 6,664,000,000$ in 1967 to $\$ 13,726,867,000$ in 1985 in 1967 prices. Projected and published figures are similar until 1973, where projected figures are slightly below the published figures.

Wage and salary payments are estimated as total wage and salary payments and wage and salary payments by sector. Total wage and salary payments in $0 k l a h o m a$ are expected to increase from $\$ 4,057,000,000$ in 1967 to $\$ 8,093,948,000$ in 1985 in constant 1967 prices. Published data figures are very similar to the simulation projections in total wage and salary payments in each sector.

Proprietor income is estimated as agricultural and non-agricultural. Total proprietor income is expected to decrease from $\$ 863,000,000$ in 1967 to $\$ 782,900,000$ in 1985 in constant 1967 prices. Proprietor income is difficult to estimate. It fluctuates very much from one year to another. Published and projected figures in proprietor income are close until 1973, where they differ considerably. This is due to the fact that some sectors' products experienced unusually high prices--such as agricultural sectors and the mining sector--in 1973. Proprietor income in agriculture is expected to increase from $\$ 292,000,000$ in 1967 to $\$ 336,434,000$ in 1985 in constant 1967 prices. Non-agricultural

proprietor income is expected to decrease from $\$ 570,000,000$ in 1967 to $\$ 446,466,000$ in 1985 due to a decline in the proprietor income rates. Comparison of the proprietor income figures obtained from published data indicates the big jump which occurred in 1973 was mainly in the agricultural sectors.

Other labor income is expected to increase from $\$ 194,000,000$ to $\$ 1,054,167,000 ;$ property income is expected to increase from $\$ 1,059,000,000$ to $\$ 1,759,869,000$; and transfer payments are expected to increase from $\$ 696,000,000$ to $\$ 2,457,051,000$ from 1967 through 1985, respectively.

## E. Projections of Other Economic Variables

State and local government expenditures are estimated in five components: education expenditures, highway expenditures, public welfare, health and hospitals, and other state and local expenditures. These variables are projected through 1985, and presented in Table XXXII. Education expenditures are expected to increase from $\$ 433,035,000$ in 1968 to $\$ 1,006,295,000$ in 1985 ; highway expenditures from $\$ 185,375,000$ in 1968 to $\$ 237,566,000$ in 1985; pub1ic welfare expenditures from $\$ 199,657,000$ in 1968 to $\$ 374,434,000$ in 1985; health and hospital expenditures from $\$ 68,132,000$ in 1968 to $\$ 174,385,000$ in 1985 ; and other state and local expenditures from $\$ 249,170,000$ in 1968 to $\$ 616,436,000$ in 1985; where all values are in 1967 prices.

Table XXXIII presents estimates of state and local government revenues from 1968 through 1985. All of the variables in this table are expected to increase from 1968 through 1985 in 1967 prices. The increases are state sales tax from $\$ 74,013,000$ to $\$ 115,504,000$;

gasoline, fuels excise, and special fuels use tax from $\$ 76,453,000$ to $\$ 96,474,000$; individual and corporation income tax from $\$ 70,245,000$ to $\$ 184,507,000$; other state and local taxes from $\$ 184,158,000$ to $\$ 323,304,000$; federal aid to the state and local government from $\$ 277,994,000$ to $\$ 632,389,000$; and other state and local revenues from $\$ 245,337,000$ to $\$ 589,571,000$. Total state and local government revenues are expected to increase from $\$ 928,200,000$ in 1968 to $\$ 1,941,749,000$ in 1985.

Estimates of disposable income, personal income per capita, gross state product, and total federal revenues collected in Oklahoma are presented in Table XXXIV. The expected increases of these variables from 1968 to 1985 in 1967 prices are:disposable income, which is defined as total personal income minus federal personal taxes and state and local personal taxes,from $\$ 5,898,017,000$ to $\$ 11,077,498,000 ;$ personal income per capita, which is defined as total personal income divided by population,from $\$ 2,754$ to $\$ 4,635$; gross state product, which is defined as value added for business sectors plus federal government and state and local government wage and salary payments, from $\$ 8,700,860,000$ to $\$ 15,251,511,000$; and total federal revenues, which include individual income tax, corporation income tax, and all other federal taxes, from $\$ 1,359,185,000$ to $\$ 2,668,728,000$; respectively.

## CHAPTER VII

ECONOMIC IMPACT ANALYSIS BY USING THE SIMULATION MODEL

In this chapter, the impact of a proposed army ammunition plant on the State economy is analyzed. The effects of this plant are measured in terms of new employment and income generated through 1985.

## A. The Situation

There is a proposal to construct an army ammunition plant in McAlester, Oklahoma. This plant will produce ordnance materials. For this analysis, the construction of the plant is assumed to start in 1976 and is expected to be completed in five years. The construction cost is expected to be about $\$ 450,000,000$ in current dollars. It is assumed that the plant will begin producing at full capacity in 1981. Expected production employment is 1200 full-time employees.

The impact of the ammunition plant on the State economy is analyzed in two phases: (1) construction phase, and (2) production phase. Construction cost of the plant is evenly distributed over the construction period. Each year's construction expenditure is entered into the model as additional new investment (see equation 5.1) in the other manufacturing industries sector (sector 13) in 1967 prices. Production in the other manufacturing industries sector is initiated in 1981 with 1200 new employees.

The two phases of the plant have different impacts on the State's
economy. During the first year of construction, only the direct and indirect effects from capital formation occur. ${ }^{1}$ During the second through fifth years of construction, the direct and indirect effects from capital formation occur due to new investment; however, another effect which is referred to as the induced capacity effect is created. Induced capacity effect is created because of the increased demand for additional goods and services from all other sectors as a result of this capital formation. Other sectors need to increase their capacity in order to produce the additional goods. The direct and indirect capital effects become zero as soon as the construction is over; however, it takes a period of years for the induced capacity effect to approach zero.

During the first year of the production phase, the direct and indirect effects arise. The direct effect measures the economic activity generated directly in the other manufacturing industries sector due to increased sector production. The indirect effects arise as the other manufacturing industries sector increases production demands additional goods and services from all other sectors. These sectors, in turn, increase their demands for goods and services from other industries. The reverberations continue until the economy is completely adjusted. The indirect effects include all reverberations of the increased production.

During each year (starting from the second year of production), another impact arises. This is referred to as induced consumption effect. The induced consumption effect arises as consumers have more
$1_{\text {See Doeksen, Gerald A., and Dean F. Schreiner, "Investments in }}$ Agricultural Processing for Rural Development in Oklahoma," [6] for explanation of short, intermediate, and long-run effects of an investment.
money to spend for goods and services, and continues on into the longrun period.

## B. The Results

The results of the impact of the proposed army ammunition plant in terms of employment and income are presented in Table XXXV. The first column of this table indicates the change in total employment due to the proposed plant. Change in total employment column presents the total change in employment due to both construction phase and production phase. Since the production does not occur until 1981, years 1976 through 1980 of this column indicate the change in total employment as a result of construction only. Years 1981 through 1985 indicate the change in total employment of both production phase and construction phase. The only impact left over in this period from the construction phase is the induced capacity effect. Only the direct effect and the indirect effects occur from the production phase in 1981. However, change in total employment column for 1982 through 1985 indicates the direct effect, the indirect effects, and the induced consumption effect of the production phase as well as induced capacity effect of the construction phase. For instance, total Oklahoma employment in 1976 is expected to increase by 3,128 as a result of the direct effect which arises from the new capital formation in the other manufacturing industries sector. The change in the State employment is expected to be 5,327 in $1977,5,644$ in 1978, 5,159 in 1979, and 4,945 in 1980. A11 of these changes in employment figures indicate both the direct capital effect and the induced capacity effect. The expected change in Oklahoma employment in 1981 is 4,041, which indicates the direct effect and the
indirect effects, both due to production, and the induced capacity effect, due to construction. Oklahoma employment is expected to increase by: 4,107 in 1982; 4,187 in 1983; 4,275 in 1984; and 4,358 in 1985 as a result of ammunition plants.

TABLE XXXV

CHANGES IN TOTAL EMPLOYMENT AND TOTAL PERSONAL INCOME AS A RESULT OF CONSTRUCTING ARMY AMMUNITION PLANT, OKLAHOMA, 1976-1985

| Year | Change in <br> Total Employment | Change in Total Personal <br> Income in Current Prices |
| :---: | :---: | :---: |
|  | $(1)$ | $(2)$ |
| 1976 | 3,128 | $\$ 27,263,000$ |
| 1977 | 5,327 | $46,341,000$ |
| 1978 | 5,644 | $49,112,000$ |
| 1979 | 5,159 | $44,855,000$ |
| 1981 | 4,945 | $43,437,000$ |
| 1982 | 4,041 | $36,759,000$ |
| 1983 | 4,107 | $37,744,000$ |
| 1984 | 4,187 | $38,790,000$ |
| 1985 | 4,275 | $39,930,000$ |
|  | 4,358 | $41,047,000$ |

The employment multiplier which is obtained by dividing the change in total employment by the production employment directly hired by the producing sector is obtained as 3.63 in 1985. This implies that for every production employee hired by the other manufacturing industries sector, the total State employment is increased by 3.63.

The second column of Table $X X X V$ indicates the expected change in total personal income in the State as a result of the ammition plant
in current prices. The interpretation of this column is very similar to the first column of the same table. For instance, total personal income is expected to increase by $\$ 27,263,000$ in 1976 as a result of the direct capital effect. The expected increases in total personal income in Oklahoma are: $\$ 46,341,000$ in 1977; $\$ 49,112,000$ in 1978; $\$ 44,855,000$ in 1979 ; and $\$ 43,437,000$ in 1980. A11 of these expected changes in income arise from the total impact of the direct capital effect and the induced capacity effect. The expected increase in income in 1981 is $\$ 36,759,000$ which indicates the total impact of the direct effect and the indirect effects from the production phase and the induced capacity effect from the construction phase. The expected increases in the State's personal income in 1982 through 1985 are: \$37,744,000; $\$ 38,790,000 ; \$ 39,930,000$; and $\$ 41,047,000$ in current prices, respectively. Each of these figures represents the total impact of the induced capacity effect, the direct effect, the indirect effects, and the induced consumption effect on income in Oklahoma.

The income multiplier, defined as change in total personal income in Oklahoma divided by the wage and salary income of the proposed 1,200 production employees in the other manufacturing industries sector, is obtained as 3.11 in 1985. This implies that every dollar spent as wage and salary payments in the other manufacturing industries sector generates \$3.11 in total personal income in Oklahoma in 1985.

The impact of the ammunition plant on employment in Oklahoma is further analyzed in terms of manpower needs. Table XXXVI contains data which summarizes the results of this analysis. The occupation of the jobs created directly, indirectly, and induced are exemplified. Not only is total employment given by wage and salary employment and

proprietor employment, but the occupation of the wage and salary job is given. For instance, in 1985, the expected increase in the number of : engineers (occupation group 1) is 51, scientists (occupation group 2) is 8, technicians (occupation group 3) is 75, etc. Miscellaneous operatives (occupation group 24) indicate the highest number of expected employment increase at 847 in 1985. Total wage and salary employment is expected to increase by 3,610 ; total proprietorship employment by 748; and total employment by 4,358 in Oklahoma in 1985.

The impact of the ammunition plant on the total federal revenues, state sales taxes, and state income taxes are presented in Table XXXVII. As a result of constructing this army plant, total federal revenues are expected to increase in current dollars by $\$ 5,180,000$ in 1976; by $\$ 8,805,000$ in $1977 ;$ by $\$ 9,333,000$ in 1978; etc. Expected increases in total federal revenues through 1985 are given in the first column of Table XXVII. The second column of the same table presents the expected increases in the state sales tax collections as a result of the army plant. For instance, expected increases in the State sales tax in current dollars are $\$ 164,000$ in 1976; $\$ 279,000$ in 1977; $\$ 295,000$ in 1978; etc. The third column of Table XXXVII presents the expected increases in the State income tax collections as a result of constructing the ammunition plant in current dollars from 1976 through 1985. For instance, expected increases in the state income tax collections are $\$ 451,000$ in 1976; \$769,000 in 1977; \$815,000 in 1978; etc.
C. Other Evaluation Uses of the Model

Impact analysis of the McAlester army ammunition plant provides only an example of the many evaluation possibilities which can be
analyzed by utilizing the Oklahoma simulation model. One possibility is using the simulation model to analyze the impact of other industrial changes or expansions. The impact of not only bringing a new industry into the economy, but expansion of existing industries can also be analyzed. Derivation of employment and income multipliers for each sector provides a comparison of expected changes in terms of employment and income generated under various investment strategies.

TABLE XXXVII
Changes in total federal revenues, state sales tax, and State income tax as a result of constructing army AMMUNITION PLANT, OKLAHOMA, 1976-1985

| Year | Changes in |  |  |
| :---: | :---: | :---: | :---: |
|  | Total Federal Revenues | State Sales Tax | State Income Tax |
|  | (1) | (2) | (3) |
| 1976 | \$5,180,000 | \$164,000 | \$451,000 |
| 1977 | 8,805,000 | 279,000 | 769,000 |
| 1978 | 9,333,000 | 295,000 | 815,000 |
| 1979 | 8,553,000 | 272,000 | 746,000 |
| 1980 | 8,253,000 | 262,000 | 719,000 |
| 1981 | 7,000,000 | 221,000 | 610,000 |
| 1982 | 7,173,000 | 229,000 | 626,000 |
| 1983 | 7,371,000 | 233,000 | 643,000 |
| 1984 | 7,586,000 | 240,000 | 662,000 |
| 1985 | 7,808,000 | 248,000 | 681,000 |

Another evaluation possibility which can be analyzed through this model is measuring the impact of alternative government programs in
the State. The impact of increased or decreased federal expenditures or revenues can be measured in terms of created new jobs and income. Implementation of various state and local government programs have different impacts on the economy. The Oklahoma simulation model can also be used to compare the impact of these programs.

## CHAPTER VIII

SUMMARY, IMPLICATION AND LIMITATIONS

## A. Summary

The main purpose of the study is to provide a dynamic analysis that will provide economic projections and will be useful in evaluating development strategies. Agricultural and industrial businesses can find the study useful in planning their operations and investments. Government administrators can find it useful in evaluating the impact of governmental policies. The major objective of this study is to develop a social accounting system for Oklahoma for 1967 and to utilize this information to develop an economic model for purposes of projecting economic variables and evaluating planning strategies. The social accounting system is constructed by using secondary data. State economic activities are aggregated into 17 endogenous and five exogenous sectors. The endogenous sectors include two agricultural sectors, one mining sector, nine manufacturing sectors, and five service-type sectors.

The social accounting system for Oklahoma for 1967 is presented in four major accounts: (1) the interindustry account, (2) the capital account, (3) the human resource account, and (4) the government account. The interindustry account is the core of the entire study. The capital account, the human resource account, and the government account are connected to the interindustry account.

The interindustry account of the Oklahoma social accounting system consists of three basic parts: a transaction or flow table, a direct coefficients table, and a direct and indirect coefficients table. The transaction table forms the base of the interindustry account and other tables are derived directly from it. The transaction table represents a double entry accounting system as sales and purchases of each sector are included in the table. The direct coefficients reveal the direct dependence of each sector on all other sectors, since they indicate input requirements per dollar of output. The direct and indirect coefficients indicate the total change which includes direct and indirect effects in input requirements as a result of a one-dollar change in final demand.

The capital account includes six basic parts: a capital coefficient matrix, capacity levels, capital-output ratios, a capital stock matrix, a capital unit matrix, and depreciation coefficients. The capital coefficient matrix forms the core of this account. The capital coefficients indicate the amount of capital goods required from each row sector for every dollar's worth of capital expenditures made by each column sector. Capacity operating levels for 1967 in each sector are estimated by using employment data. Capital-output ratios are defined as the ratio of the total cost of plant and equipment to output at capacity. The total values of capital goods and compositions are given in the capital stock matrix. Capital unit matrix indicates the amount of capital goods required from every sector to produce one unit of output capacity in each sector. Depreciation coefficients are estimated as the ratio of depreciation to depreciable assets.

The human resource account is an important part of a social
accounting system. This section is constructed in three major parts: (1) employment, (2) population, and (3) income. The employment section contains five main parts: (1) a labor coefficient matrix, (2) outputemployment ratios, (3) a sector employment matrix, (4) a labor stock matrix, and (5) a total Oklahoma employment by occupation matrix. Labor coefficients indicate change in labor requirements in each occupation group as a result of one unit change in the total employment in that column sector. Output-employment ratios indicate the value of output produced by each employee in each sector. Sector employment matrix presents the total employment (wage and salary employment plus proprietor employment) in each sector. Labor stock matrix gives the occupational mix of employment by sector. Total Oklahoma employment by occupation matrix indicates the total number of employees in each occupation group.

Oklahoma population analysis is based on total employment in Oklahoma. Assuming perfect mobility of labor and full employment, population is estimated by assuming that a specific portion of the population is employed. Income section includes sector wage and salary rates, and proprietor income rates, sector wage and salary incomes and proprietor incomes, total personal income, and disposable income. Sector wage and salary rates and proprietor income rates indicate the wage and salary payments and proprietor income per employee, respectively, in each sector. Sector wage and salary income and proprietor income presents the total wage and salary payments and proprietor income, respectively, in each sector. Total personal income is determined by summation of sector wage and salary incomes, sector proprietor incomes, property income, other labor income, and transfer payments and subtraction of personal contributions to social insurance. Disposable income is estimated by
subtracting personal taxes from total personal income.
Government account is constructed around two groups of activities: (1) federal government, and (2) state and local government. Each government sector is analyzed in two basic parts: (1) revenues, and (2) expenditures. Federal government revenues are estimated by a regression approach. Federal government expenditures are estimated from previous year's expenditures. State and local government revenues are estimated by regression approach in six components: (1) state sales tax, (2) gasoline and fuels excise tax, (3) income tax, (4) all other state and local taxes, (5) federal aid to state and local governments, and (6) all other state and local revenues. State and local government expenditures are analyzed in a similar way to the state and local revenues. The components of state and local expenditures include: (1) education expenditures, (2) highway expenditures, (3) public welfare, (4) health and hospitals, and (5) all other state and local expenditures.

The simulation model is formulated around the basic Leontief inputoutput model. The model is constructed in a recursive sequence and consists of 62 major equations. Most of the major equations are disaggregated into sub-equations; for example, one sub-equation for each endogenous sector. Each major equation in the employment section is disaggregated into sub-equations to estimate the employment by occupation for each sector. Thus, the entire system includes over 1,500 equations. The model is formulated in Fortran and is run on the computer at a relatively low cost, since it requires only slightly more than two minutes of central processing unit (CPU) time. Researchers can experiment with the model by changing variables and measuring their impact since the computer program is relatively inexpensive.
B. Implication

Employment and income are projected by sector. Total employment is expected to increase by 53.4 percent from 1967 to 1985 . Wage and salary employment is expected to increase by 57.2 percent, whereas proprietor employment is expected to increase by 40.6 percent. The slow rate of growth in proprietor employment is due basically to the decline in the number of proprietors in agriculture.

Wage and salary employment is expected to increase in all endogenous sectors except in agriculture (sectors $1+2$ ), mining (sector 3), and lumber and wood products (sector 7). The rate of decrease is 26.3 percent in mining, 19.5 percent in agriculture, and 21.3 percent in lumber and wood products from 1967 to 1985 . The expected rate of increase is greatest in the apparel and other products sector (sector 8) by 238.5 percent; next greatest is the construction sector (sector 4) by 154.2 percent in the same period. The rates of increase in wage and salary employment of the other manufacturing sectors are: food and kindred products (sector 5) by 11.6 percent; petroleum refining (sector 6) by 5.5 percent; printing and publishing (sector 9 ) by 72.8 percent; machinery and electrical machinery (sector 10 ) by 92.1 percent; transportation equipment (sector 11) by 46.7 percent; primary and fabricated metal products (sector 12) by 28.6 percent; and other manufacturing industries (sector 13) by 29.7 percent from 1967 to 1985. Expected rates of increase in wage and salary employment of the other servicetype sectors are:transportation, communication, and public utilities (sector 14) by 28.7 percent; wholesale and retail trade (sector 15) by 68.9 percent; finance, insurance, and real estate (sector 16) by 104.3
percent; and services (sector 17) by 105.9 percent in the simulation period of 1967 to 1985. In the same period, wage and salary employment in the federal government sector (sector 18) is expected to decrease by 19.6 percent, while in state and local government sector (sector 19) is expected to increase by 56.0 percent. Total wage and salary employment in service-type sectors is expected to increase by 84.1 percent, whereas for manufacturing sectors the expected rate of increase is 53.7 percent from 1967 to 1985.

Wage and salary employment in all occupation groups are expected to increase from 1967 to 1985. The expected rates of increase are: engineers (occupation group 1) by 24.0 percent; scientists (occupation group 2) by 7.4 percent; technicians (occupation group 3) by 63.1 percent; computer and other machine specialists (occupation group 4) by 27.1 percent; economists, planners, and teachers (occupation group 5) by 83.2 percent; miscellaneous artists (occupation group 6) by 63.9 percent; other professional and technical workers (occupation group 7) by 51.5 percent; financial managers (occupation group 8) by 67.3 percent; other managers and administrators (occupation group 9) by 57.6 percent; sales workers (occupation group 10) by 71.5 percent; secretaries (occupation group 11) by 56.8 percent; other machine operators (occupation group 12) by 47.9 percent; other clerical workers (occupation group 13) by 49.6 percent; construction traders (occupation group 14) by 103.9 percent; foremen (occupation group 15) by 42.7 percent; metal workers (occupation group 16) by 48.7 percent; mechanics and repairmen (occupation group 17) by 41.5 percent; printing trades (occupation group 18) by 63.9 percent; electrical workers (occupation group 19) by 36.4 percent; other miscellaneous craftsmen (occupation group 20) by 49.5 percent; metal and
machine shop workers (occupation group 21) by 52.4 percent; textile machine workers (occupation group 22) by 29.5 percent; final processors (occupation group 23) by 55.4 percent; miscellaneous operatives (occupation group 24) by 50.5 percent; janitorial workers (occupation group 25) by 70.8 percent; food workers (occupation group 26) by 78.4 percent; personnel service workers (occupation group 27) by 102.1 percent; pub1ic service workers (occupation group 28) by 58.2 percent; and laborers (occupation group 29) by 36.6 percent.

Among income projections from 1967 to 1985, total personal income is expected to increase by 106.0 percent, wage and salary payments by 99.5 percent, other labor income by 443.4 percent, property income by 66.2 percent, and transfer payments by 253.0 percent. Sectors' wage and salary payments follow patterns which are similar to employment projections. Proprietor income is expected to decline from 1967 to 1985 by 9.3 percent.

Oklahoma population is projected to increase by 19 percent from 1967 to 1985 with an annual average rate of increase of approximately . 98 percent.

Federal government revenues are expected to increase by 94.5 percent, whereas governmental (federal government and state and local government) wage and salary payments are to increase by 61.6 percent in the same 18 -year period. Total state and local government revenues from 1967 to 1985 are expected to increase by 116.2 percent while rates of increase for individual components of state and local revenues are: state sales taxes by 60.1 percent, gasoline fuels excise and special fuels use tax by 23.8 percent, individual and corporation income tax by 199.9 percent, other state and local taxes by 85.2 percent, federal aid
to state and local governments by 122.2 percent, and other state and local revenues by 159.4 percent. Total state and local government expenditures are expected to increase from 1967 to 1985 by 107.4 percent, whereas the rates of increase for individual components of expenditures are: education expenditures by 114.6 percent, highway expenditures by 33.4 percent, public welfare expenditures by 79.9 percent, health and hospital expenditures by 167.5 percent, and other state and local expenditures by 155.5 percent.

The 0klahoma simulation model can be used as a tool to measure the impact of various development strategies. This study analyzes only one of these possibilities as an example.

The impact analysis consists of measuring the effects on the State's income and employment of the proposed army ammunition plant in McAlester, Oklahoma. New employment which is expected to be generated by this plant is around 5,000 each year during the construction period and around 4,000 during the production period. Employment multiplier is found to be 3.63 ; this implies that every additional production worker hired by this plant increases the total employment in the State by 3.63 in 1985. New income generated from this plant is expected to be $\$ 41,047,000$ in 1985 in current prices. Income multiplier is found to be 3.11, which implies that every additional dollar of wage and salary payment made for the production workers of this plant is expected to generate $\$ 3.11$ in total personal income (in constant 1967 dollars) in the State in 1985. Because of this plant, total wage and salary employment is expected to increase by 3,610 ; total proprietorship employment by 748; and total employment by 4,358 in 1985. The largest expectincrease is in miscellaneous operatives (occupation group 24), where

847 additional employees are expected to be hired in 1985. It is followed by other clerical workers (occupation group 13) with 350 employees, construction traders (occupation group 12) with 220 , sales workers (occupation group 10) with 215, and laborers (occupation group 29) with 212 .

## C. Limitations

Limitations for the study area arise from (1) data limitations and (2) model assumptions. Data limitations occur since a vast amount of data is required and time and funds prohibit the collection of primary data. With primary data, the model could have been developed in greater detail, permitting greater analysis. For instance, exports and imports are computed as net exports and imports in the present model. With primary data, exports and imports could be analyzed as gross elements. In addition, data limitations faced the aggregation of economic activity into 17 sectors and 29 occupations. The empirical results apply to these sectors and occupations groups and not to specific industries and occupations. Again, the problem of "tradeoff" is faced in deciding how much time and money is available for collection of primary data versus using secondary data and having less model refinement.

Model assumptions also limit the study. A major model limitation is that the simulation model is built around the input-output model and thus has basic input-output assumptions. The most serious input-output assumption is that the technical coefficients are fixed which implies no input substitution and technology is constant. For short-run projections, fixed coefficient assumption is not a major limitation. However, for long-run purposes, if the economy is experiencing rapid
changes, the assumption can limit usefulness of results. To provide for some adjustment in technology, capital-output ratios and laboroutput ratios change annually to reflect improved technology.

Most of the future research needs are exemplified directly from the data limitations and model assumptions. Additional research is needed to estimate the technical coefficients with projected changes in prices of inputs and outputs. In this way, a new interindustry flow table needs to be constructed with every set of price projections which may be estimated exogenously. Thus, not only the model will become more dynamic and realistic, but also the area where this model can be utilized to measure the impact of various governmental decisions will be enlarged. Such an analysis will also allow the researcher to project economic variables under the substitutability conditions of factors of production. For instance, recent increases in oil prices have affected Oklahoma's economy by: (1) impact on oil production, (2) an impact on consumption. Oil producers have been encouraged to produce more oil, whereas oil consumers have been discouraged. The impact of various government programs under changing oil prices can be analyzed if appropriate adjustments are made with the model.

Additional refinement of the human resource account is also possible. In such an addition, population may be estimated in a demographic sector by components and age coharts. Net migration may be incorporated into the model as a separate component and may be treated as a difference between the two population projections obtained from the demographic sector and from the model endogenously. It is also possible to analyze migration in two components: (1) inmigration and (2) outmigration. Movement of population in different age coharts can be seen clearly in such an analysis.

APPENDIX A

## METHODS AND DATA USED FOR CONSTRUCTION OF THE INTERINDUSTRY FLOW TABLE

The Oklahoma Model has 17 endogenous and five exogenous sectors. Sectors are defined according to the classification used by the Bureau of Labor Statistics. Classification of endogenous sectors is summarized in Appendix Table XXXVIII. All data are in 1967 prices.
I. Definitions, Methodologies, and Sources Used in Deriving the Endogenous Sectors

Sectors 1 and 2: Livestock and Livestock
Products and Crops

Output is defined as the value of all agricultural commodities produced on the farm in 1967 plus the value of government payments and the rental value received. Estimated values are as follows:

| Livestock and livestock products | $\$ 467,823,000$ |
| :--- | ---: |
| Crops | $417,412,000$ |
| Government payments | $112,344,000$ |
| Farm rental received | $36,400,000$ |
| Total | $\$ 1,033,979,000$ |

Detailed information for the value of agricultural commodities grown on Oklahoma farms in 1967 is given in [31] and is as follows:

Livestock and livestock products

| Cattle and calves | $\$ 345,721,000$ |
| :--- | ---: |
| Sheep and wool | $1,956,000$ |
| Hogs | $25,956,000$ |
| Milk, cream, milkfat | $67,491,000$ |
| Poultry | $13,561,000$ |
| Eggs | $12,576,000$ |
| Honey and beeswax | 562,000 |
| Total |  |
|  |  |

TABLE XXXVIII

CLASSIFICATION OF ENDOGENOUS SECTORS, OKLAHOMA MODEL
Oklahoma Model Included in the Sector

1. Livestock and livestock products
(SIC 0132, pt. 014, 0133, 0134, pt. 014; 0135, 0136 0139, pt. 014, 0193, pt. 0729)
2. Crops
(SIC 1000 except the ones given in section 1 )
3. Mining
(SIC 2000)
4. Construction
(SIC 3000)
(a) cattle and calves
(b) dairy products
(c) hogs
(d) poultry products
(e) sheep and lambs
(f) wool
(g) other livestock products
(a) wheat
(b) cotton and lint
(c) hay
(d) peanuts
(e) cottonseed
(f) sorghum
(g) broomcorn
(h) oats
(i) alfalfa seed
(j) corn
(k) barley
(1) watermelons
(m) spinach
(n) soybeans
(o) rye
(p) fruits and nuts
(q) other crop products
(r) forestry and fishery products
(s) agricultural, forestry, and fishery services
(a) crude petroleum and natural gas
(b) metal mining
(c) bituminous coal and lignite mining
(d) non-metallic minerals, except fuels
(a) maintenance and repair construction
(b) new construction
5. Food and kindred products (SIC 4120)
(a) meat products
(b) dairy products
(c) canned and frozen food
(d) grain mill products
(e) bakery products

Table XXXVIII (Continued)

|  | Oklahoma Model | Included in the Sector |
| :---: | :---: | :---: |
|  |  | (f) confectionery and related products <br> (g) beverage industries <br> (h) miscellaneous food preparation <br> (i) prepared feed for animals |
|  | Petroleum refining and related industries (SIC 4129) | (a) petroleum refining <br> (b) paving and roofing materials <br> (c) petroleum products, N.E.C. |
|  | Lumber and wood, furniture and fixtures, and paper and allied prod. (SIC 4124, 4125, 4126) | (a) lumber and wood products <br> (b) furniture and fixtures <br> (c) paper and allied products |
|  | Apparel and other finished products made from fabrics and similar materials (SIC 4123) | (a) clothing and fabricated products produced by sewing purchased fab rics and related materials |
|  | Printing and publishing (SIC 4127) | (a) printing by one or more of the common processes <br> (b) services for the printing trade <br> (c) publishing newspapers, books, and periodicals |
|  | Machinery and electrical machinery <br> (SIC 4135, 4136) | (a) farm machinery and equipment <br> (b) construction and like equipment <br> (c) metal working machinery <br> (d) electrical household appliances <br> (e) other machinery which utilizes electrical energy, transmission and transformation |
| 11. | Transportation equipment (SIC 4137) | (a) motor vehicles <br> (b) aircrafts <br> (c) ships and boats <br> (d) railroad equipment <br> (e) miscellaneous transportation equipment |
|  | Primary and fabricated metal products (SIC 4133, 4134) | (a) primary metal industries <br> (b) fabricated metal products |
| 13. | $\begin{aligned} & \text { Other manufacturing } \\ & \text { (SIC 4119, 4121, } \\ & \text { 4122, 4128, 4130, } \\ & 4131,4132,4138 \text {, } \\ & 4139 \text { ) } \end{aligned}$ | (a) ordnance and accessories <br> (b) tobacco manufacturers <br> (c) chemicals and allied products <br> (d) rubber and plastic products <br> (e) leather and leather products |

Table XXXVIII (Continued)

| Oklahoma Model |  | Included in the Sector |
| :---: | :---: | :---: |
|  |  | (f) stone, clay, and glass products <br> (g) instruments and related products <br> (h) miscellaneous manufacturing |
| 14. | ```Transportation, communica- tion, and public utilities (SIC 5000)``` | (a) local passenger transportation <br> (b) trucking and warehousing <br> (c) pipeline transportation <br> (d) transportation services <br> (e) communication <br> (f) electric, gas, and sanitary services |
| 15. | ```Wholesale and retail trade (SIC 6000)``` | (a) motor vehicles and automotive equipment <br> (b) drugs, chemicals, and allied products <br> (c) dry goods and apparel <br> (d) groceries and related products <br> (e) farm products <br> (f) electrical goods <br> (g) hardware, plumbing, and heating equipment <br> (h) machinery equipment and supplies <br> (i) miscellaneous wholesalers <br> (j) building materials and farm equipment <br> (k) general merchandise <br> (1) food <br> (m) automotive dealers and service stations <br> (n) apparel and accessories <br> (o) furniture and home furnishings <br> (p) eating and drinking places <br> (q) miscellaneous retail stores <br> (r) retail stores, N.E.C. |
| 16. | ```Finance, insurance, and real estate (SIC 7000)``` | (a) banking <br> (b) credit agencies and other loan banks <br> (c) insurance carriers <br> (d) insurance agents, brokers, and services |
| 17. | Services (SIC 8000) | (a) hotels and other lodging places <br> (b) personal services <br> (c) miscellaneous business services <br> (d) auto repair and services <br> (e) motion pictures <br> (f) amusements, recreation services <br> (g) medical services <br> (h) other professional services |

## Crops

| Wheat | $\$ 130,373,000$ |
| :--- | ---: |
| Oats | $3,317,000$ |
| Barley | $4,845,000$ |
| Rye | 565,000 |
| Corn for grain | $1,524,000$ |
| Sorghum for grain | $25,802,000$ |
| Sorghum for forage | $7,704,000$ |
| Sorghum for silage | $8,100,000$ |
| Cotton lint | $19,633,000$ |
| Cottonseed | $4,771,000$ |
| Soybeans for beans | $8,940,000$ |
| Peanuts for nuts | $22,374,000$ |
| Alfalfa seed | $1,032,000$ |
| All others | $178,432,000$ |
|  |  |
|  |  |
| Total | $\$ 417,412,000$ |

Government payments to farmers and farm rental income are also available in [31] and [51]. All government payments are for crops, except $\$ 111,000$ which is received by farmers for wool [31] and [52]. Farm rental received is allocated by assuming each sector's share in proportion to output of the livestock and crops sectors.

Livestock Sector Crops Sector
Livestock and livestock products \$467,823,000

Crops
Government payments
Farm rental received

## Total

$\begin{array}{rr} \\ 111,000 & \$ 17,412,000 \\ 112,233,000\end{array}$
$19,236,000 \quad 17,164,000$
$\$ 487,170,000 \$ 546,809,000$

Publications from the Oklahoma Department of Agriculture and the United States Department of Agriculture are the primary sources for input data which is much more difficult to obtain.

Fuels, repairs, and maintenance expenses are considered as operating expenses. Source [83] gives estimates of purchased fuel. Data ${ }^{1}$ in [56]
$1_{\text {Use of data given in [56] needs to be clarified. This information }}$ used to determine the input structure before imports are considered. After distributing inputs, residuals are computed. In case of negative residual--which implies sector is importing--every entry in each row is adjusted by this residual, Data in Table II presents these adjusted input entries. The calculation of exports and imports is explained in more detail in the last section of this appendix.
are used for estimating the amount of agricultural inputs from the construction sector as repair and maintenance. The remaining amount of operation expenses is allocated to the machinery sector.

| Total Operating Expenses | $\$ 73,381,500$ |
| :---: | ---: |
| Less petroleum expenses | $41,274,800$ |
| Less repair and maintenance | $9,398,600$ |

Amount allocated to machinery sector $\$ 22,708,100$
Information in [56] is used to allocate petroleum, machinery, and construction inputs between the two agricultural sectors.

The remaining agricultural inputs reported in [51] are allocated into the livestock and crops sectors as follows:

|  | Livestock | Crops | Total |
| :---: | :---: | :---: | :---: |
| Fuels, rep. and maintenance | \$4,376,100 | \$ 25,742,400 | \$ $30,118,500$ |
| Fertilizer |  | 6,739,600 | 6,739,600 |
| Feed grains | 2,189,700 |  | 2,189,700 |
| Feed (commercial) | 7,493,800 |  | 7,493,800 |
| Livestock | 3,799,900 |  | 3,799,900 |
| Seed |  | 289,500 | 289,500 |
| Seed (commercial) |  | 2,663,100 | 2,663,100 |
|  | \$17,859,500 | \$35,434,600 | \$53,294,100 |

Transportation and taxes, as reported in [25] are included in these margin totals. Wholesale and retail trade costs may be estimated by subtracting transportation costs and taxes from these margin totals [56] . The results are as follows:

|  | Livestock | Crops | Total |
| :---: | :---: | :---: | :---: |
| Margin Total | \$17,859,500 | \$35,434,600 | \$ 53,294,100 |
| Less transportation | 5,086,200 | 10,091,300 | 15,177,500 |
| Less taxes | 2,303,900 | 4,571,100 | 6,875,000 |
| Wholesale and retail trade | \$10,469,400 | \$20,772,200 | \$31,241,600 |

Expenditures for communication and public utilities are added to the above estimated transportation costs, in order to estimate the
purchases of livestock and crops sectors from the transportation, communication, and public utilities sector.

|  | Livestock | Crops | Total |
| :---: | :---: | :---: | :---: |
| Transportation charges | \$5,086,200 | \$10,091,300 | \$15,177,500 |
| Electricity charges | 7,134,124 | 6,387,718 | 13,521,842 |
| Telephone charges | 2,260,935 | 2,024,385 | 4,285,320 |
| Total | \$14,481,259 | \$18,503,403 | \$32,984,662 |

Average monthly electrical charges are obtained from [50] and the number of farms is obtained from [31]. Average monthly phone bill paid by farmers by regions and the estimated number of farms with phones in Oklahoma are obtained from [49]. The distribution of totals is made by relative share of output of livestock and crops sectors.

Information in [56] is utilized for estimates of the purchases of the agricultural sectors from finance, insurance, and real estate; mining; and services sectors. Depreciation for the livestock and the crops sectors is estimated by using depreciation rates which are ratio of depreciation to depreciable assets during 1967. These ratios are obtained from [102]. Multiplying these ratios by sectors capital stock, which is obtained as a product of sector output and capital output ratio from [101], yields the value of depreciation for each sector. Estimated value of depreciation is $\$ 42,330,000$ for livestock and $\$ 72,098,000$ for the crops sector.

The estimation of purchases by livestock and crops sectors from federal government are obtained from [94], [55], and [39]. For computation procedures, purchases are divided into five subsectors:
(1) corporation income tax, (2) individual income and employment tax, (3) estate tax, (4) gift tax, and (5) excise tax. For state and local government purchases, sources [31] , [55], [39], and [61] are utilized.

State and local purchases are divided into: (1) property tax, (2) federal government payments to state and local governments, (3) charges and miscellaneous, (4) utility revenue, (5) insurance trust revenue, and (6) other state and local government taxes. Other state and local taxes include sales and gross receipts, insurance trust revenue, motor vehicle licenses, and other miscellaneous taxes.

The estimation of purchases by the agricultural sectors from households are obtained from [31], [52], and [55]. Household purchases are divided into two major components: wage and salaries, and other income. The four subcomponents of other income include: other labor income, proprietor income, property income, and transfer payments. For the purchases of imports, the procedure which is explained in export section at the end of this appendix is used. The values of imports are $\$ 6,743,000$ for livestock sector, and $\$ 26,713,000$ for the crops sector. Agricultural sectors' purchases from federal government, state and local government, and households are given in Table XXXIX.

## Sector 3: Mining

Output of the mining sector is defined as the value of receipts plus the value of minerals used in the mining industry. Data concerning value of production are available in [68] and [88]. Output is obtained as follows:

## Production

| Oil and gas |  |
| :--- | ---: |
| Metal mining |  |
| Bituminous coal and lignite <br> Non-metal minerals, except mining <br> fuel | $1,192,500,000$ |
| $\quad$ | $6,200,000$ |
| $\quad$ Value of production | $19,000,000$ |

TABLE XXXIX

## Output

Value of production 1,223,100,000
Less mining included in manufacturing 7,100,000
Value of output \$1,216,000,000
The distribution of this output into endogenous sectors is made by using the information available in [56]. Purchases of mining sector from federal government are estimated from [101], [94], [55], and [39]; from state and local government are obtained from [55], [39], [61], [31], [62], and [63]; from households are determined from [101], [55], [68], [33], and [87]. Mining sector's purchases from federal government, state and local government, and households are given in Table XL. The value of imports by mining sector is estimated as $\$ 133,359,000$. The value of depreciation is estimated by utilizing the information given in [101] and [102] at $\$ 77,657,000$.

## Sector 4: Construction

Output of construction sector is defined as the value of receipts of the industries in this sector. No other source indicates this sector's output in Oklahoma; therefore, it needs to be estimated from national data. It is assumed that the ratio of output in Oklahoma to output in the United States is the same as the ratio of employment in Oklahoma to employment in the United States. By using this method and the information from [56], [87], and [34], the construction sector's output is estimated as $\$ 1,028,358,000$.

Purchases of the construction sector from federal government, state and local government, and household sectors are given in Table XL. They are determined by using various sources: [101], [94], [55], and

The value of imports by construction sector is estimated at $\$ 202,144,000$ and the value of depreciation, which is estimated by using data given in [102] and [101] is estimated at $\$ 18,211,000$.

Sectors 5 through 13: Manufacturing

Manufacturing activities are classified into nine sectors. The descriptions of these sectors are outlined in Table XXXVIII. Because of the similarities of the techniques used to estimate outputs and inputs, these sectors are discussed jointly.

Output of each of these sectors is defined as the value of production of the industries in that sector. Each sector's output is estimated by adding the value of shipments and the value of inventory change. Output estimates of manufacturing sectors are given in Table XLI. Estimates of output and some of the inputs are obtained by using the information found in the four columns of the United States Census of Manufacturing [64], [65], [66], and [67].

The amount spent for services from the government sectors is assumed to be equal to taxes paid. Data which are used to estimate federal government taxes are found in [101], [94], [55], and [39]. State and local government taxes are estimated from [55], [31], [68], [62] , [39], [61], and[63]. Payments of the manufacturing sectors to households are estimated by using information available in [101], [63], [55], [33], [61], [-76], [68], and[87]. Table XLII displays these estimates.

The value of depreciation for each sector is estimated by using that sector's depreciation rate, capital-output ratio, and output from [101] and [102].

The values of depreciation and the values of imports for the manufacturing sectors are given in Table XLIII.

## Sectors 14 through 17: Services

The discussions of these sectors are given jointly because similar techniques are used to estimate each sector's output and inputs. This section includes the discussion of transportation, communication, and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services sectors.

Output for the transportation, communication, and public utilities sector is defined as the value of receipts received. No source indicates the output directly; therefore, it needs to be estimated from national data. For this estimate, it is assumed that the ratio of output between Oklahoma and the United States is the same as the ratio of employment between Oklahoma and the United States. Employment statistics are available in [87] and [75]. Sector output for the United States is given in [56]. By this method, output is estimated at $\$ 1,306,821,000$.

Output for the wholesale and retail sector is defined as the value of services performed in handling goods. To estimate the output for this sector, the same procedure which is used for transportation sector is applied. By using the information given in [56], [75], and [87], output estimate is obtained as $\$ 1,862,361,000$.

The output of finance, insurance, and real estate sector is defined

TABLE XLIII
THE VALUES OF DEPRECIATION AND IMPORTS FOR THE MANUFACTURING SECTORS, OKLAHOMA, 1967

|  | Sector | Value of Imports | Value of Depreciation |
| :---: | :---: | :---: | :---: |
| 5 | Food and kindred products | \$81,622,000 | \$11,419,000 |
| 6 | Petroleum refining and related industries | 30,803,000 | 30,359,000 |
| 7 | Lumber and wood, furniture and fixtures, paper and allied products | 21,617,000 | 3,311,000 |
| 8 | Apparel and other finished products made from fabrics and similar materials | 19,785,000 | 644,000 |
| 9 | Printing, publishing, and allied industries | 20,852,000 | 2,864,000 |
| 10 | Machinery, electrical machinery equipment and supplies | 92,154,000 | 17,420,000 |
| 11 | Transportation equipment | 38,949,000 | 6,348,000 |
| 12 | Primary and fabricated metal products industries except ordnance, machinery, and transportation equipment | 59,609,000 | 12,547,000 |
| 13 | Miscellaneous and all other manufacturing industries | 74,878,000 | 15,343,000 |

as the value of receipts received for services of this sector. A similar procedure to the earlier two sectors is applied. Since property income is included in the household row sector, the output of finance, insurance, and real estate sector needs to be adjusted. A similar adjustment is also needed for the row sector of finance, insurance, and real estate sector. By using the information available in [56], [87], [75] and [55], the output of this sector is estimated at $\$ 1,028,369,000$. Services sector's output is defined as the amount paid to the industries of this sector for their services. By using the employment ratio and statistics given in [56], [75], and [87], the output of services sector is estimated at $\$ 1,471,529,000$.

Input data for these sectors are much more difficult to obtain. National coefficients are used for most of these inputs' estimates. These sectors purchases from primary inputs sectors are estimated individually. Taxes paid by these sectors are assumed equal to the value of services received. Data in [101], [94], [55], and [39] yield federal taxes paid by these sectors, while data in [31], [68], [62], [55], [39], [61], and [63] yield the estimates of state and local taxes of the same sectors. Data on payments to households are available in $[101],[55],[33],[87],[61],[63],[76]$, and [68]. Purchases of these sectors from government and household sectors are given in Table XLIV. Depreciation of transportation, communication, and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services sectors are estimated by using the data in [101] and [102] at: $\$ 132,735,000 ; \$ 69,523,000 ; \$ 25,614,000 ;$ and $\$ 96,615,000 ;$ respectively. The values of imports of the sectors are estimated at: $\$ 60,763,000 ;$ $\$ 114,790,000 ; \$ 90,011,000$; and $133,062,000$, respectively.

| Total | \$480,480,000 | \$1,036,020,000 | \$ $335,951,000$ | \$772,589,000 |

## II. Definitions, Methodologies, and Sources Used in Deriving the Exogenous Sectors

## Federal Government Sector

Total federal government outlays in Oklahoma are assumed to be equal to the output of the federal government sector. Since there is not any source indicating the total federal outlays in Oklahoma in 1967, they are estimated by using the information in [84]. This estimate is obtained as $\$ 2,280,885,000$. For exogenous sectors, total output does not need to be equal to total inputs. This requires individual estimation of expenditures. Exogenous sectors purchases from federal government, state and local government, and households are estimated individually as they are in endogenous sectors. The sources which are used to estimate the purchases from federal government are [94], [55], and [39]; from state and local government are [31], [68], [62], [55], [.39], [61], and [63]; and from households are [34], [55], and [54]. These estimates are given in Table XLV. Estimates of purchases by federal government from endogenous sectors are obtained by using Polenske study [42]. Federal government purchases of imports are estimated at \$200,669,000.

## State and Local Government Sector

Governments of state, county, municipal, special districts, and school districts are included in this sector. Output for this sector is defined as the sum of the expenditures of included government units in Oklahoma. Sector output is obtained by using the information in [56], [75], and [34] as $\$ 1,157,000,000$. Estimates of purchases by

| :---: | ---: | ---: |
|  | $\$ 1,109,528,000$ | $\$ 609,542,000$ |

state and local government sector from federal government are obtained from [94], [55], and [39]; from state and local government are obtained from $[31],[68],[62],[55],[39],[61]$, and $[63]$; and from households are obtained from [55], [52], [54], and [61]. These estimates are also given in Table XLV. Purchases by state and local government from endogenous sectors are estimated by using the information available in the Polenske study [42]. The value of imports purchased by state and local government is estimated at $\$ 97,705,000$.

## Private Capital Formation Sector

The total amount of capital invested by the private sectors are included in this sector's output. This output consists of new capital formation, capital replacement needs, and residential housing construction. Since new capital formation figures are not available, they must be estimated. This estimation is made by using capital-output ratios and the change of output in respective sectors. Multiplication of these estimates yields the total capital need by each sector. Each sector's total capital need is distributed into producing sectors by using that sector's column vector of capital coefficient matrix. A row-wise addition of this new matrix results in a column vector of new capital formation. Similarly, capital coefficient matrix is used to distribute the estimates of capital replacement needs for each sector. The column vector which is obtained by totaling all individual columns of this matrix indicates the replacement capital purchases from respective sectors. Residential housing construction estimates are obtained from [75]. Summation of new capital formation column, capital replacement column, and addition of the value of residential housing construction
to the construction sector represents the total value of the purchases made by private capital formation sector from each producing sector. The total output of this sector is estimated as $\$ 1,142,208,000$. This final column provides the base for the column vector in Table II. The column vector of private capital formation in Table II is obtained after adjustments made for imports.

## Household Sector

Individuals' expenditures for goods and services constitute the purchases of the household sector. Household income includes wages and salaries, proprietor income, other labor income, property income, and transfer payments. Household expenditures are estimated in two groups. In the first group, purchases of households; from federal government--by using the sources [94], [55], and [39]; from state and local government--by using the sources [55], [39], [62], and [63] ; and from households--by using the sources [55], [62], and [76]--are obtained. In the second group, household expenditres on endogenous sectors are estimated. For these estimates, the ratio of population between Oklahoma and the United States is used as proxy. Sources [56] and [75] are used for expenditures on endogenous sectors. Sector expenditures total $\$ 7,060,166,000$.

Household payments of federal government taxes are as follows:

$$
\begin{array}{cr}
\text { Individual income tax } & \$ 362,693,000 \\
\text { Social security } & 204,000,000 \\
\text { Other federal taxes } & 194,215,000 \\
\hline \text { Total } & \$ 760,908,000
\end{array}
$$

Other federal taxes include estate tax, gift tax, and excise tax.
Household payments as state and local government taxes are as

## follows:

$$
\begin{array}{lr}
\text { Property tax } & \$ 132,395,000 \\
\text { Utility revenue charges and miscellaneous } & 135,317,000 \\
\text { Other state and local government taxes } & 215,223,000 \\
\quad \text { Total }
\end{array}
$$

Households property income within themselves are estimated from [62] and $[76]$ at $\$ 44,521,000$. The value of imports is estimated at $\$ 1,443,997,000$.

## Export Sector

Exports and imports are computed as residuals. First, and interindustry table is completed using the entries whose derivation is discussed in this appendix. The demand for the product is obtained by adding the row entries. Then this sum is subtracted from the estimate of sector output. If the residual is positive, it implies a surplus; whereas a negative residual implies a shortage. Surplus values are assumed to be equal to sector exports, while shortages indicate the sector imports. Export and import figures obtained in this way indicate only the 'net'values. Export figures are given in column 22 of Table II for livestock (sector 1), crops (sector 2), mining (sector 3), and petroleum refining (sector 6) sectors.

The 'het" import figures are distributed to the various sectors by assuming each sector's imports are equal to the percentage it requires from the total demand for the products of that sector. The amount of imports for each sector is then subtracted from the amount that the purchases sectors purchased from that producing sector. Total value of sector imports is obtained by totaling the values of imports for every column and entered as row 20 of Table II. In this way, a new interindustry table is constructed and presented in Table II.

APPENDIX B

CLASSIFICATION OF OCCUPATION GROUPS, OKLAHOMA MODEL

## TABLE XLVI

CLASSIFICATION OF OCCUPATION GROUPS, OKLAHOMA MODEL

VITA

A. Unal Sarigedik<br>Candidate for the Degree of<br>Doctor of Philosophy

Thesis: A SIMULATION MODEL FOR ANALYZING ALTERNATIVE CHANGES OF THE OKLAHOMA ECONOMY AND PROJECTING ECONOMIC VARIABLES FROM 1967 TO 1985

Major Field: Agricultural Economics
Biographical:
Personal Data: Born in Ankara, Turkey, May 15, 1943, the son of Mr. and Mrs. M. Seyfeddin Sarigedik.

Education: Graduated from Gazi Lisesi, Ankara, Turkey, in 1960; received Agriculture Engineer degree in Agricultural Economics from the University of Ankara in 1964; received Master of Science degree in Agricultural Economics from Oklahoma State University in 1972; completed requirements for the Doctor of Philosophy degree at Oklahoma State University in December, 1975.

Professional Experience: Planner and Economic Analyst, Turkish Ministry of Agriculture, 1964-1969; U.S.A.I.D. participant, the Department of Agricultural Economics, Oklahoma State University, 1970-1971; Graduate Research Assistant, Department of Agricultural Economics, Oklahoma State University, 1972-1975.

[^0]:    ${ }^{1}$ Numerals appearing in [ ] refer to bibliography references in the dissertation.

[^1]:    ${ }^{1}$ Stock-flow relationship is described as the increase in flows which results from a given increase in stocks. Flow-stock relationship refers to the induced effect on capital formation of an increased demand in the regions output.
    ${ }^{2}$ Data sources are discussed in detail in Chapters III through $V$ and in Appendix A.

[^2]:    ${ }^{2}$ Since Table IV does not have any negative yalue, Hawkins-Simmon condition is met so the coefficients are stable [26, p. 27].

[^3]:    4 The capacity-estimating procedure by the Wharton School was tested against other techniques by Krishnamurty [18]. It was found to be as good as other sophisticated techniques and much easier to derive, especially for the manufacturing and service-type sectors. For agriculture, other procedures which measure such variables as land availability and use might provide a more accurate estimate.

[^4]:    ${ }^{2}$ All annual growth rates are estimated by utilizing logarithmic approach.

[^5]:    $1_{\text {For }}$ details of the occupational aggregation, see Appendix B.
