## DNMR STUDY OF THE THERMODYNAMIC AND KINETIC

PARAMETERS ASSOCIATED WITH THE RING
REVERSAL OF A SPIRO SYSTEM CON-

RAINING AN $\alpha$-METHYLENE- $\gamma-$

BUTYROLACTONE RING

## Thesis Approved:

## ACKNOWLEDGMENTS

I take great pleasure in expressing my heartfelt gratitude to Dr. K. Darrell Berlin for his support, guidance and friendship during the extent of this project. I also would like to extend my thanks to the members of Dr. Berlin's research group for their helpful suggestions and enjoyable discussions over every facet of this work.

I gratefully acknowledge the financial support granted me by the Department of Chemistry at Oklahoma State University, the National Cancer Institute and by Phillips Petroleum Company during the summers of 1976 and 1977.

I wish to thank Dr. Dick van der Helm, at The University of Oklahoma for his expertise in obtaining the $X$-ray data. I would also like to thank Mr. Stan Sigle for his help in obtaining the NMR data and his assistance on various technical aspects of this work.

I would also like to thank the support staff of the Department of Chemistry at Oklahoma State University for their sympathetic aid during the course of this project. I also give a special note of gratitude to Mrs. Dolores Behrens for typing this manuscript.

I thank my parents, Mr. and Mrs. A. D. O'Donnell, for the love and devotion given so generously to me during these many years. Finally, I wish to dedicate the whole of this work to my wife, Joyce, and my son, Sean, for the little things that mean so much to me.

HISTORICAL

```
Structure and Activity of Selected Natural
Products Containing an \alpha-Methylene-\gamma-
butyrolactone Ring
```

More than 500 different sesquiterpene lactones have been isolated over the last two decades and many have shown a wide range in degree and type of biological activity. 79 From a variety of systems uncovered the highest level of biological activity has been displayed by those with the $\alpha$-methylene butyrolactone unit. While most of these units have been part of a large carbocyclic skeleton, the simplest $\alpha$-methylene lactone structure isolated from a plant source was tulipalin A (1a). 5,88 This compound and the hydroxy homolog tulipalin $B$ (1b) may have as

1a $R=H ; \quad 1 b R=O H$
precursors in the tissue of young tulips the glucosides tuliposide $A$ (2a) and tuliposide B (2b) which degrade to the lactones. ${ }^{5}$ Lactones $1 a$ and $1 b$ have been shown to be a fungitoxic component from the skin of the young tulip, which may be a factor in the prevention of fungal infections. ${ }^{5}$

In 1959, S. M. Kupchan and co-workers began to screen the crude extracts of a variety of plants available in the vicinity of the University of Wisconsin at Madison and from cooperative sources outside the United States with the expectation that a few active components might have potential use as antitumor agents. ${ }^{59}$. This "modest" beginning led to the isolation and identification of over sixty active compounds. Included in these compounds were several sequiterpene $\alpha$-methylene lactones which displayed a considerable degree of cytotoxicity against certain KB cell lines. Two sesquiterpene dilactones, elephantin (3) and elephantopin ( $\underset{\sim}{4}$ ), were isolated from the plant Elephantopus elatus Bertol, family Compositae, and were shown to be very active against

Walker intramuscular carcinosarcoma 256.

Three novel, halogen-containing sesquiterpene lactones (the first halogen sesquiterpenes ever isolated) were extracted along with five other active lactones from the plant Eupatorium rotundifolium L., also of the family Compositae. ${ }^{62}$ While all eight lactones showed cytotoxicity against a KB cell line, only euparotin acetate ( ${\underset{\sim}{~) ~}}_{\text {) and eupachlorin }}$ acetate (6) were tested in vivo and were shown to be active [T/C $=23$ for $75 \mathrm{mg} / \mathrm{kg}$ and 42 for $400 \mathrm{mg} / \mathrm{kg}$, respectively; where $\mathrm{T} / \mathrm{C}=$ weight of the tumor in the test animal/weight of the tumor in the control] against Walker $256 .{ }^{62}$ All eight of the isolated lactones contained the same basic guaianolide $\underset{\sim}{7}$ carbocyclic backbone with the $\alpha$-methylene- $\gamma$ butyrolactone unit present in each molecule.

The dilactones vernolepin ( $\underset{\sim}{8}$ ) and veromenin ( $\underset{\sim}{9}$ ) were isolated from the plant Veronia hymenolepus A. Rich. and differ only in the position

of the $\gamma$-1actone ring. ${ }^{61}$ These compounds are novel in that they contain both a $\gamma$ - and $\delta$-lactone unit with an $\alpha$-methylene group. Later studies of the reactivity of $\underset{\sim}{8}$ with model biological nucleophiles revealed the $\alpha$-methylene- $\gamma$-butyrolactone probably was the reactive moiety. ${ }^{59}$ For example, the reactivity of 8 with amino acid cysteine was facile but in contrast, lysine or guanine were very slow to react. 59,82 Nevertheless, the action of the lactone in vivo could involve a cysteine unit as a coreactant.

Of all the many sesquiterpene lactones isolated to date, the majority have come from the extracts from the species of the family Compositae. Structural relationships between compounds isolated from two different plants within a tribe have been suggested as a means to screen certain classifications. ${ }^{29}$ The similarity in structure of sesquiterpene lactones found within a plant tribe has thus been linked to a human allergenic response to the members in the tribe, and, in each case, an $\alpha$-methylene lactone was indicated as the active unit. ${ }^{79}$ Current research directed primarily toward investigating possible chemotaxonomic classification of species has resulted in the isolation of several new $\alpha$-methylene lactones. ${ }^{9}$ This strongly suggests that attempted isolation of these compounds as potential antitumor agents
should be concentrated within a certain species. This is especially true when compounds obtained from members of a species show specific antitumor activity since the basic carbocyclic structure (eg. 7) appears to remain essentially unchanged for compounds isolated from a particular species. Functional groups attached to the periphery of the basic structure may change (eg. $\underset{\sim}{5}$ and $\underset{\sim}{6}$ ) and could alter the activity in a very positive manner, as exemplified by the different activities of compounds $\underset{\sim}{5}$ and $\underset{\sim}{6} .{ }^{62}$ A recent study suggested that synthetic modifications of certain natural products may be a viable way of producing quantities of less available lactone-containing chemicals. ${ }^{69}$

It is also intriguing to note that $\alpha$-methylene- $\gamma$-aminobutyric acid (10), the decarboxylation produce of $\alpha$-methyleneglutamic acid (11), has

been isolated from plant sources. ${ }^{23,38}$ These compounds were also reported to have been isolated from tulips. ${ }^{23}$ One can easily envision the closure of $\alpha$-methylene- $\gamma$-aminobutyric acid to the five-membered lactam (12), the nitrogen analog of compound $1 \mathrm{\sim}$. Since $\underset{\sim}{1 a}$ is stored

12
in the tulip as the glucoside, it is not unreasonable that 12 might also exist as the glucoside. The fact that this glucoside has not been isolated may not be surprising considering the reported ease by which the glucoside bond is broken in the case of 2a. ${ }^{5,88}$ Amazingly, no large scale attempts have been made to isolate or synthesize $\alpha$-methyl-ene- $\gamma$-butyrolactams with the intent to examine cytotoxicity in spite of the obvious similarity to the $\alpha$-methylene- $\gamma$-butyrolactones.

## Synthesis of Selected Compounds Containing an $\alpha$-Methylene- $\gamma$-butryolactone Ring

The biological activity of the many natural products in which the active unit is an $\alpha$-methylene- $\gamma$-butyrolactone ring has prompted an intense effort to synthesize a wide range of compounds with this group as a major unit. ${ }^{27,31}$ While it is beyond the scope of this discussion to present a review of the literature in this area, a few of the many synthetic techniques will be presented as examples of the variety of approaches applied to the problem.

One general method of synthesizing the $\alpha$-methylene- $\gamma$-butyrolactone unit has involved the formation of the $\alpha$-methylene group on a preformed butyrolactone synthon. A recent synthesis of tulipalin A ( $\alpha$-methylene-$\gamma$-butyrolactone, $\underset{\sim}{\text { 1a }}$ ) clearly demonstrated this approach. ${ }^{43}$ The simple lactone $\underset{\sim}{13}$ was converted to $\underset{\sim}{14}$ via standard techniques. The sodium salt 14 was then reductively aminated with sodium cyanoborohydride to give $\underset{\sim}{15}$, which was then quaternized with methyl iodide. Treatment of the quaternary ammonium salt with aqueous $\mathrm{NaHCO}_{3}$ effected an elimination of trimethylamine to give $\underset{\sim}{\sim}$ (70\%).

Because of the high reactivity of the $\alpha$-methylene- $\gamma$-butyrolactone unit, the creation of the $\alpha$-methylene group is often left to the latter part of a synthesis, especially if it is lengthy. Grieco and coworkers in the elegant synthesis of ( $\ddagger$ )-vernolepin (8) ${ }^{33}$ employed a bis- $\alpha-$ hydroxymethylation procedure which was ultimately followed by mesylation of the tetrahydropyrany1 (THP) ether $\underset{\sim}{6}$ in pyridine at $5^{\circ} \mathrm{C}$. The resulting bismesylation product 17 was added to a benzene solution of diazabicyclo[5.4.0]undec-5-ene (DBU) which promoted elimination. Hydrolysis of the THP ether yielded ( $\pm$ )-vernolepin (8).

In the synthesis of ( + )-costunolide (21), Grieco and Nishizawa ${ }^{32}$ formed the methylene group using selenenylation of lactone $\underset{\sim}{18}$ to give seleneylated lactone $\underset{\sim}{19}$. This product underwent oxidative elimination to 20 , which suffered thermolysis in a GLC column to yield (+)-costunolide (21).

These methods for $\alpha$-methylenation, as well as several specific modifications thereof, have been successfully used in the synthesis of other natural products. 34,35 A clever and efficient technique was recently reported ${ }^{85}$ for effecting $\alpha$-methylenation using diethyl oxalate and sodium hydride to generate the $\alpha$-g1yoxylate ester (eg. 22). Subsequent reaction of 22 with a solution of diethylamine and aqueous

formaldehyde gave the appropriate substituted $\alpha$-methylene- $\gamma$-butyrolactone 23 in quantitative yield.

The $\alpha$-methylene group may also be incorporated prior to lactonization, but care must be exercised in the eventual lactonization step to avoid polymerization of this highly reactive functional group. 82 Perhaps the method of widest utility in this regard involves the Reformatsky reaction involving a key precursor ethy1 $\alpha$-(bromomethyl)acrylate (24) which, however, is somewhat difficult to prepare and
polymerizes readily. ${ }^{21} \ddot{\text { Ohler }}$ and co-workers synthesized a variety of substituted $\alpha$-methylene- $\gamma$-butyrolactones via this procedure. ${ }^{75}$ As an example, benzaldehyde was allowed to react with 24 and Zn in THF $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}$ for 1 hour at $50^{\circ} \mathrm{C}$. The reaction mixture was cooled, then poured into dilute ice-cold HC1; the product 25 was isolated in near quantitative yield. Rosowsky and co-workers ${ }^{82}$ also used this synthesis to obtain a variety of spiro $\alpha$-methylene- $\gamma$-butyrolactones. However, the yields were poor, primarily due to the heating conditions used for the lactonization step. In most cases, the product polymerized either upon boiling in concentrated HC 1 or during the subsequent distillation. Ramalingam and Berlin ${ }^{80}$ circumvented this problem and reported high yields of several spiro lactones using ice-cold $5 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ as the lactonizing agent in the final step. Several substituted heterocyclic ketones were allowed to react with 24 to give lactones containing heteroatoms in the carbon skeleton (eg. 26). Recently Lee and coworkers ${ }^{66}$ reported the synthesis of several uracil and thymine $\alpha$-methylene- $\gamma$-butyrolactones using 24 in a very similar fashion. Lactone 27 was synthesized in this manner (90\%), for example. These

26

compounds, as well as certain previously synthesized steroidal $\alpha$-methyl-ene- $\gamma$-butyrolactones, ${ }^{65}$ showed significant cytotoxicity against Walker 256 carcinosarcoma.

There are also several syntheses which involve organometallic complexes or intermediates which may be used to synthesize $\alpha$-methylene lactones. Among these are procedures which involve allyl nickle complexes, ${ }^{39}$ substituted propenyl cuprates and corresponding 1ithio compounds ${ }^{70}$ as well as certain palladium complex intermediates. ${ }^{73}$ While these synthetic methods have proven useful in certain reactions, they. have not been widely adopted.

Several specific compounds have also been prepared recently which bear a striking resemblance to the butyrolactone system. A series of $\alpha$-methylenelactams were recorded in 1974, ${ }^{64}$ but surprisingly no other studies have appeared with this heterocyclic system. The natural occurring $\alpha$-methylene ketone ( $\pm$ )-methylenomycin $A$. (28) a known antibiotic, was recently synthesized. ${ }^{83}$ The strong resemblance to sarkomycin (29), a known antitumor agent, ${ }^{90}$ suggested that the $\alpha$-methylene

28

ketone function may be a viable alternative unit to the $\alpha$-methylene lactone as an antitumor active group. Indeed, among the many cytotoxic $\alpha$-methylene lactones listed in a recent review were several natural products containing both the $\alpha$-methylene lactone and the $\alpha$-methylene ketone functions. 79

DNMR Studies of Selected Systems

Thermodynamic Studies

The use of dynamic nuclear magnetic resonsance (DNMR) spectroscopy for analysis of physical properties of dynamic organic systems was first proposed in 1953 by Gutowsky and co-workers. ${ }^{37}$ Little was done at that time to test this proposal, primarily because of the primative state of the art in instrumentation. Only four years later Nair and Roberts ${ }^{74}$ demonstrated for the first time that NMR spectroscopy could be used in conformational analysis of certain geminal difluoro compounds (eg. 30). Lemieux and co-workers ${ }^{67}$ suggested that the method might be

applicable to the study of six-membered ring compounds in carbohydrate chemistry. The first attempt at a semi-quantitative analysis of the thermodynamic properties of a two-site exchange process was Eliel's examination of the ring reversal in bromocyclohexane ( $\underset{\sim}{31} \underset{\sim}{32}$ ) in 1959. ${ }^{16}$ The methine proton of the cyclohexyl system appeared as a lone

31

32
signal at room temperature, even though the earlier work by Lemieux and co-workers ${ }^{67}$ had clearly demonstrated that protons in an axial conformation ( $\mathrm{H}_{\mathrm{a}}$ in $\underset{\sim}{32}$ ) were magnetically different from protons in an equatorial conformation ( $\mathrm{H}_{\mathrm{e}}$ in $\underset{\sim}{31}$ ) and therefore should give rise to separate signals in the NMR spectrum. Using Gutowsky and Saika's ${ }^{37}$ earlier theory, Eliel derived the following equation:

$$
K_{e q}=\left(\delta_{a}-\delta\right) /\left(\delta-\delta_{e}\right)
$$

$K_{e q}=$ the equilibrium constant for the reversal
$\delta_{a}=$ chemical shift of pure axial proton ( $H_{a}$ in 32)
$\delta_{e}=$ chemical shift of pure equatorial proton ( $\mathrm{H}_{\mathrm{e}}$ in $\underset{\sim}{31}$ )
$\delta=$ chemical shift of the equilibrating system.

At room temperature, the chemical shifts for the axial and equatorial protons were not obtainable for bromocyclohexane and thus the shifts of the appropriate protons in the conformationally "locked" and
isomeric 1-bromo-4-t-butylcyclohexanes, 33 and $\underset{\sim}{34}$, were used. Interestingly, Eliel attempted to cool bromocyclohexane to a point at which signals for individual conformers could be observed in the spectrum. He stated, however, that ". . . even at low temperatures the signal

33

34
for the tertiary hydrogen was not split and thus the position for the signals corresponding to the pure conformations could not be observed. ${ }^{16}$ Only a year later, Berlin and Jensen ${ }^{6}$ achieved temperatures low enough to detect separate signals in the NMR spectra for the methine proton in several mono-substituted cyclohexanes. The chemical shift method outlined above was then used to calculate the equilibrium constant using the actual chemical shifts of the individual conformers at low temperatures. More important, the actual relative concentrations of the two conformers could be measured directly from the low temperature spectra using the integrated areas under the respective peaks, thus providing a second method of analysis. The equilibrium constant could then be calculated by:

$$
\mathrm{K}_{\mathrm{eq}}=[\mathrm{A}] /[\mathrm{B}]
$$

$K_{e q}=$ the equilibrium constant for the reversal process
$[A]=$ the integrated area for the signal corresponding to the axial conformer
$[B]=$ the integrated area for the signal corresponding to the equatorial conformer.

This represented the more theoretically satisfying approach for determination of the equilibrium constant for the reversal process since actual parameters for the equilibrating system were used and not those of model compounds. Unfortunately, values could be obtained only at very low temperatures ( $<-80^{\circ} \mathrm{C}$ ) which were experimentally difficult to achieve and maintain. In spite of the theoretical and experimental difficulties associated with these methods, both have been extensively used to evaluate the thermodynamic character of a large number of ringreversal processes particularly in cyclohexanes. ${ }^{25,40}$ Although several other NMR methods have been employed, ${ }^{25}$ these two have been the most popular.

Criticism of the chemical shift method focuses around the use of proton signals in model biased compounds such as 33 and 34 for comparison with the chemical shifts of the corresponding protons for the pure axial and pure equatorial conformers in the equilibrating system. 42,48 Jensen and Beck ${ }^{47}$ compared the chemical shifts of the methine protons for several mono-substituted cyclohexanes with that corresponding signal in the 4 -t-butyl analogues at very low temperatures to distinguish signals for both conformers in the equilibrating system (eg. $\underset{\sim}{31} \underset{\sim}{32}$ ). Comparison of the $H(1)$ proton signals for the axial and equatorial conformers in the equilibrating system with the corresponding signals for the axial and equatorial isomers in the spectra of the analogous biased systems (eg. 33 and 34 ) showed that distinct shift differences existed. Therefore, the authors considered the
simple method invalid. Eliel, ${ }^{18}$ in an article published at about the same time, used a series of gem-substituted compounds (eg. $35 \underset{\sim}{\gtrless} \underset{\sim}{36}$ ) and their 4-t-butyl analogues to defend the method. The chemical shifts of the methoxy groups in the equilibrating systems were shown to lie exactly midway between the signals corresponding to the axial

35

36
and equatorial methoxy groups in the 4 -t-butyl system 37 . The combined results of these studies suggested that, while the method may be

37
of doubtful validity for the compounds studied by Jensen and Beck ${ }^{47}$ under the specific conditions employed, insulation of the object protons in systems such as $3 \underset{\sim}{\lessgtr} \underset{\sim}{36}$ may effectively cancel the influence of the t-butyl group. A later study by Ford and Allinger strongly supported this observation. ${ }^{22}$ Jensen and Beck ${ }^{47}$ then applied a correction to the method for the mono-substituted systems. It was observed that the temperature dependence of the chemical shifts for protons in the biased systems paralleled the dependence shown by the equilibrating systems at very low temperatures. This parallel relationship
was assumed to be true at higher temperatures, and thus the chemical shifts of protons in the actual axial and equatorial substituted conformers in the unbiased system were extrapolated to the higher (ca. $25^{\circ} \mathrm{C}$ ) temperatures. For example, in the case of bromocyclohexane $(31 \underset{\sim}{*} 32)$ and cis- and trans-4-t-butylbromocyclohexane (33 and 34 ),

31

32

33
34
the chemical shifts of the axial methine protons $\left(H_{a}\right)$ for 32 and 34 were shown to differ by a constant 4 Hz for temperatures from -84 to $-102{ }^{\circ} \mathrm{C}$. A similar difference $(5.5 \mathrm{~Hz})$ was shown to exist for the equatorial signals $\left(\mathrm{H}_{\mathrm{e}}\right)$ in 31 and 33 . The chemical shifts of the corresponding protons in the t-butyl isomers 33 and 34 at $-102^{\circ} \mathrm{C}$ were 456.0 and 382.1 Hz (relative to internal TMS), respectively. At $+24^{\circ} \mathrm{C}$, the shifts were 452.9 and 380.4 Hz , respectively. To compensate for this obvious temperature dependence, the differences observed at the very low temperatures between 31 and 33 and between 32 and 34 were applied at the higher temperature. The chemical shift
method was then used with these "corrected" values. The $\Delta G^{0}$ value obtained in this manner ( $0.55 \mathrm{kcal} / \mathrm{mol}$ ) compared favorably with the value obtained at $-8{ }^{\circ} \mathrm{C}$ using integrated areas ( $0.49 \mathrm{kcal} / \mathrm{mol}$ ). The value for $\Delta G^{0}$ obtained by using the "uncorrected" chemical shifts for 33 and $\underset{\sim}{34}$ was given as $0.35 \mathrm{kcal} / \mathrm{mol}$. The corrected method assumes the parallel shift relationships (observed over an $18^{\circ}$ temperature range for the systems $\underset{\sim}{31} \underset{\sim}{~} 32,33$ and 34 ) extends over a temperature range of $128^{\circ}$. At the present time, insufficient data exist to make an assessment of the validity of this correction on a general basis. Furthermore, recent studies 78,89 (see below) suggest that the original shift method may be valid in specific cases; hence the need exists to evaluate each case on its own merit.

Several spiro systems have been investigated by NMR methods in which both conformers have a non-hydrogen, axial substituent ( $38 \underset{\sim}{7} \underset{\sim}{39}$ ).

38

where $X \neq Y$

In 1971, Jones and co-workers 50,52 examined a series of spirosubstituted 1-t-butylpiperidines $(\underset{\sim}{4} \underset{\sim}{~ 41})$ in which the authors have assumed that atomic inversion about the nitrogen atom occurs simultaneously and that this inversion is facile compared to the ring reversal. It was anticipated that the use of spiro compounds of this
type would eliminate some of the difficulties involved in comparison of the conformational analysis of 1,1-disubstituted compounds. The spiro compounds proposed could eliminate rotational isomeric contributions, provide accessible signals for investigation, and isolate the object protons from the six-membered ring. ${ }^{51}$ The method of

integrated areas at low temperature was used, and $\mathrm{K}_{\mathrm{eq}}=1.29$ was calculated for the equilibrium $40 \nsim 41$ at $30^{\circ} \mathrm{C}$ where $\mathrm{X}-\mathrm{A}-\mathrm{B}-\mathrm{Y}$ was $-\mathrm{CH}_{2}-\mathrm{NH}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}-0-50$ This corresponded to a $\Delta \mathrm{G}^{\mathrm{o}}$ of $0.12 \mathrm{kcal} / \mathrm{mol}$ in favor of the conformer with the $\mathrm{C}-0$ axial bond. In contrast, a value for $K_{e q}$ of 0.81 was calculated for the case where $X-A-B-Y$ was $-\mathrm{CH}_{2}-\mathrm{O}-\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}-\mathrm{NH}-$, corresponding to a $\Delta \mathrm{G}^{\mathrm{O}}$ of $0.12 \mathrm{kcal} / \mathrm{mol}$ in favor of the isomer with the $C-N$ bond $(Y=N$ in $\underset{\sim}{4})$ in the equatorial position.

Uebel and co-workers ${ }^{89}$ investigated the conformational equilibrium of several 1-oxaspiro 4.5 decanes $(42 \mathrm{a}-\mathrm{c} \underset{\sim}{4} 43 \mathrm{a}-\mathrm{c})$. The analysis of both $42 \mathrm{a} \rightarrow 43 \mathrm{a}$ and $42 \mathrm{c} \underset{\sim}{\leftarrow} 43 \mathrm{c}$ at low temperatures $\left(<-80^{\circ} \mathrm{C}\right)$ showed that the conformer with the axial $C-0$ band (42a and 43 c ) was favored in each case. Analysis of $\underset{\sim}{42 b} \underset{\sim}{43 b}$ showed a startling reversal of this trend. In this case, conformer 43 b was favored by $-0.13 \mathrm{kcal} / \mathrm{mol}$ at

$-80^{\circ} \mathrm{C}$ (by integrated areas) and by $-0.28 \mathrm{kcal} / \mathrm{mol}$ at $35^{\circ} \mathrm{C}$ (by uncorrected chemical shifts). This suggests that substituents alpha to the groups which occupy the axial-equatorial positions in the equilibrating system may sterically influence the equilibrium.

Picard and Moulines ${ }^{78}$ have investigated the conformational equilibrium of spiro-substituted cyc1ohexanes ( $44 \mathrm{a}, \mathrm{b} \stackrel{\vec{*}}{\leftarrow} 45 \mathrm{a}, \mathrm{b}$ ). Using bands

44

a. $\mathrm{Z}=\mathrm{CH}_{2}, \mathrm{R}=\mathrm{H}$
b. $Z=C=0, R=t-b u$
in the IR spectrum, the equilibrium $44 \mathrm{a} \stackrel{\rightarrow}{\leftarrow} 45 \mathrm{a}$ was shown to favor 44 a , by $0.46 \mathrm{kcal} / \mathrm{mol}$ at $35^{\circ} \mathrm{C}$. The two t-butyl spiro lactones 44 b and 45 b
were examined by equilibration of the isomers in $50 \% \mathrm{H}_{2} \mathrm{SO}_{4}$. Isomer 44 b was favored by $0.278 \mathrm{kca} / \mathrm{mol}$ at $55^{\circ} \mathrm{C}$.

The equilibrium of the unsaturated lactone $\underset{\sim}{46} \underset{\sim}{47}$ was also investigated by Picard and Moulines ${ }^{78}$ by the uncorrected chemical

$\stackrel{46}{\sim}$

$\stackrel{47}{\sim}$
shift method using the cis- and trans-8-t-butyl-substituted analogues to establish the chemical shifts of the axial and equatorial signals for $\mathrm{H}(4)$. A conformational preference of $0.47 \mathrm{kcal} / \mathrm{mol}$ was shown for conformer $\stackrel{46}{\sim}$ at $38^{\circ} \mathrm{C}$, in excellent agreement with the value of 0.50 kcal/mol favoring $\stackrel{46}{\sim}$ at $-95^{\circ} \mathrm{C}$ found by Uebel and co-workers ${ }^{89}$ by integrated areas.

## Kinetic Studies

Gutowsky and Saika ${ }^{37}$ apparently were the first to propose that kinetic parameters, such as the activation free energy, $\Delta G^{*}$, could be determined by the line-shape analysis of the NMR spectra of dynamic systems. In 1956, the first successful quantitative analysis was made of the internal rotational barriers for $\mathrm{N}, \underline{\mathrm{N}}$-dimethylformamide via DNMR line shape analysis. ${ }^{36}$ From this initial study, the field has expanded to include a large variety of exchange processes. It is beyond the scope of this work to describe all the theoretical aspects and
applications of DNMR in the analysis of kinetic parameters associated with exchange processes. The reader is instead referred to the excellent reviews of the area 55,87 as well as the recently published reference ${ }^{46}$ which surveys the entire subject. Specific examples of ring reversal in substituted cyclohexyl systems follow as well as a discussion of the factors which may contribute to the height of the barrier to the reversal process.

The ring reversal for cyclohexane and cyclohexane- $\mathrm{d}_{11}$ has been extensively investigated ${ }^{4}$ (the deuterated compound has a less complex spectrum, especially with deuterium decoupling, and therefore was somewhat easier to analyze). Best values for the kinetic parameters were reported ${ }^{4}$ from a compilation of these many studies. The free energy barrier to ring reversal $\left(\Delta G^{*}\right)$ was given as $10.5 \mathrm{kcal} / \mathrm{mol}$ and the enthalpy of activation $\left(\Delta H^{*}\right)$ as $10.8 \mathrm{kcal} / \mathrm{mol}$ for cyclohexane.

The kinetic parameters for a variety of substituted cyclohexanes have also been determined. ${ }^{26}$ The value for $\Delta G^{*}$ for 1,1 -dimethylcyclohexane (10.6 kcal/mol) differed only very slightly from that of cyclohexane (10.5 kcal/mol). Interestingly, a slightly higher value (10.8 kcal/mol) was determined for 1,1 -dimethoxycyclohexane. When the ${ }^{1} H$ spectra of tetra-substituted compounds $\underset{\sim}{48}$ were analyzed very carefully, a series of effects became apparent. The magnitude of the activation free energy showed a decrease for $1,1,3,3$-tetramethylcyclohexane $48 \mathrm{a}(9.6 \mathrm{kcal} / \mathrm{mol})$, suggesting that the 1,3 -interactions of the axial methyl groups destabilize the two chair conformers relative to the boat or twist boat intermediate 49. This would effectively lower the reversal barrier, resulting in the lower $\Delta G^{*}$ value.

48

49
a. $\mathrm{R}=\mathrm{CH}_{3}$
b. $\mathrm{R}=\mathrm{O}-\mathrm{CH}_{3}$

As a means of comparing the steric requirements of different groups, the 1,1 -dimethoxy-3,3-dimethylcyclohexane system 48 b was also analyzed by Friebolin and co-workers. ${ }^{26}$ The value obtained for $\Delta G{ }^{*}$ $(10.4 \mathrm{kcal} / \mathrm{mol})$ suggested that the 1,3 -interaction of the non-bonded pairs on oxygen with the methyl groups was less than that of the 1,3-methyl-methy1 interactions. Not surprising, however, was the value of $9.5 \mathrm{kcal} / \mathrm{mol}$ for the $\Delta G^{0}$ of the bis-ethylene ketal of cyclo-hexan-1,3-dione (50) which suggested that the non-bonded electronic

50
repulsions of the syn-axial oxygens shown are of the same order as 1,3-methyl-methyl interactions. Rather surprising was the observation that separate signals for the axial and equatorial groups in 51 were not detected even at temperatures as low as $-95^{\circ} \mathrm{C}$. ${ }^{26}$ This implies

51
that the activation free energy for the reversal is affected by the rotational freedom of the substituents.

The hexa-substituted cyclohexanes 52 and 53 investigated by Friebolin and co-workers ${ }^{26}$ apparently have low $\Delta G{ }^{*}$ values. Both compounds 52 and 53 failed to display separate signals for axial and equatorial conformers at temperatures as low as $-100^{\circ} \mathrm{C}$. This is apparently due to an effective lowering of the barrier so that equilibration is still rapid even at the low temperature.

$\stackrel{5}{\sim}$

53

The interesting compound $54 \underset{\sim}{4}$ which showed anomolous behavior was determined to have a free energy barrier to reversal of $\Delta G^{*}=12.0$ kcal/mol. ${ }^{26}$ Such behavior was believed due to the destabilizing affect that 1,2- and 1,4-interactions had on the possible intermediates for the reversal. Specifically, eclipsing in the boat or twist boat

54
form of 54 (eg. $\underset{\sim}{55}$ ) could raise the energy of the intermediate relative to the chair form. Analysis of these compounds using theoretical models

55
and semi-empirical calculations to derive relative conformational energies provided some support for this hypothesis. 84

Error Analysis

The linearized, relative error equation for $\Delta G^{\circ}$ can be derived from Eq. (1) :

$$
\begin{equation*}
\Delta G^{O}=-R T \ln K_{\mathrm{eq}} \tag{1}
\end{equation*}
$$

$$
\begin{aligned}
\Delta G^{O} & =\text { standard free energy } \\
R & =\text { gas constant }\left[1.987\left(10^{-3}\right) \mathrm{kcal} / \mathrm{mol} \cdot \mathrm{deg}\right]
\end{aligned}
$$

$$
\begin{aligned}
\mathrm{T} & =\text { temperature in }{ }^{\circ} \mathrm{K} \\
\mathrm{~K}_{\mathrm{eq}} & =\text { equilibrium constant }
\end{aligned}
$$

It can be shown that Eq. (2) can be derived from Eq. (1)

$$
\begin{aligned}
& \quad\left(\sigma_{\Delta G^{\mathrm{o}}} / \Delta \mathrm{G}^{\mathrm{o}}\right) \simeq\left\{\left(\sigma_{\mathrm{T}} / \mathrm{T}\right)^{2}+\left(\ln \mathrm{K}_{\mathrm{eq}}\right)^{-2}\left(\sigma \mathrm{~K}_{\mathrm{eq}} / \mathrm{K}_{\mathrm{eq}}\right)^{2}\right\}^{\frac{1}{2}} \\
& \sigma_{\Delta} \mathrm{G}^{\mathrm{o}}=\text { uncertainty in } \Delta \mathrm{G}^{\mathrm{o}} \\
& \sigma_{\mathrm{T}}=\text { uncertainty in } \mathrm{T} \\
& \sigma_{\mathrm{K}_{\mathrm{eq}}}=\text { uncertainty in } \mathrm{K}_{\mathrm{eq}}
\end{aligned}
$$

where $\Delta G^{0}, T$ and $K_{\text {eq }}$ have the same meaning as above [see page 96 for the derivation Eq. (2)]. Thus, an error in $T$ of $0.5 \%$ (at $T \simeq 180 \mathrm{~K}$ ) would be expected to result in a relative error of the same order of magnitude in $\Delta G^{\circ}$. An error of $\sim 5 \%$ in $K_{e q}\left(K_{e q} \simeq 0.8\right)$ would be expected to result in an error of $22 \%$ in $\Delta G^{\circ}$. The combined error is about $23 \%$. Therefore, it is important to measure as accurately as possible either the integrated areas or the chemical shifts but preferably both. To this end, multiple runs should be employed to help eliminate random errors and, if possible, several methods of measuring the dependent variables should be used. Temperature control is especially critical but is difficult at extremely low temperatures; hence the need exists to monitor the temperature constantly. The use of emperically derived equations which allow one to calibrate chemical shift differences of protons in known compounds (i.e. methanol or ehtylene g1ycol) with temperatures has proven most useful also. 95

The linearized relative error equation for $\Delta H^{\circ}$ is given by
Eq. (3):

$$
\begin{equation*}
\left(\sigma_{\Delta H^{o}} / \Delta H^{\mathrm{o}}\right) \simeq\left\{2 \mathrm{~T}^{2} /(\Delta \mathrm{T})^{2}\left(\sigma_{\mathrm{T}} / \mathrm{T}\right)^{2}+2\left[\Delta\left(\ln \mathrm{~K}_{\mathrm{eq}}\right)\right]^{-2}\left(\sigma_{\mathrm{K}}^{\mathrm{eq}} \text { } / \mathrm{K}_{\mathrm{eq}}\right)^{2}\right\}^{\frac{1}{2}} \tag{3}
\end{equation*}
$$

where $\Delta H^{\circ}=$ the standard enthalpy of the equilibrium, $\Delta T=$ the range of temperatures, $\Delta\left(\ln K_{e q}\right)=$ the range of $\ln K_{e q}$ and the other symbols have the same meaning as above [see page 9 ] for a derivation of Eq. (3)]. Thus a temperature range of $10^{\circ}$ and an uncertainty in $T$ of $0.5 \%$ introduces an uncertainty of $14 \%$ in $\Delta H^{\circ}$. An uncertainty of $5 \%$ in the values of $K_{e q}$ (for values of $K_{e q}$ ranging from 0.8 to 0.7 ) results in an uncertainty in $\Delta H^{\circ}$ of $53 \%$; the combined uncertainty is about 55\%. If the temperature range is 230 to $280^{\circ}$ (Kelvin), the range of $K_{e q}$ values is 0.7 to 0.6 and the uncertainties remain the same. The uncertainty values are $2.8 \%, 46 \%$ and $46 \%$, respectively. The overall error is primarily due to the small change in the value of $K_{e q}$ over the temperature range studied and the fact that $\Delta H^{0}$ is dependent upon the difference in the logarithms.

Although the instrumental problems, such as temperature control, also affect the determinations of the kinetic parameters, the typically wider range of values for the absolute rate constant for temperature ranges of 30 to $40^{\circ}$ reduces the overall relative error. One can derive the linearized, relative error equation for $\Delta G^{*}$ from the Eyring Equation (4):

$$
\begin{equation*}
k=k\left(k_{B} T / h\right) \exp \left(-\Delta G^{*} / R T\right) \tag{4}
\end{equation*}
$$

$$
\begin{aligned}
\mathrm{k} & =\text { absolute rate constant } \\
\kappa & =\text { frequency factor } \\
\mathrm{k}_{\mathrm{B}} & =\text { Boltzman constant }\left[3.2996\left(10^{-27}\right) \mathrm{kcal} / \mathrm{mol}\right]
\end{aligned}
$$

$$
\begin{aligned}
\mathrm{T} & =\text { temperature in } \mathrm{K} \\
\mathrm{G}^{*} & =\text { activation free energy } \\
\mathrm{R} & =\text { gas constant }\left[1.987\left(10^{-3}\right) \mathrm{kcal} / \mathrm{mol} \cdot \mathrm{deg}\right] \\
\mathrm{h} & =\text { Planck's constant }\left[1.5836\left(10^{-37}\right) \mathrm{kcal} \cdot \mathrm{sec}\right]
\end{aligned}
$$

The relative error can be shown to be: ${ }^{8}$

$$
\left(\sigma_{\Delta G^{*}} / \Delta G^{*}\right) \simeq\left\{\left|\ln \left(k_{B} T / h k\right)\right|^{-2}\left(\sigma_{k} / k\right)^{2}+\left(\sigma_{T} / T\right)^{2}\right\}^{\frac{1}{2}}
$$

Eq. (5)
where the symbols have their usual meanings. For the typical case where $\mathrm{T}=300 \mathrm{~K}\left(\mathrm{k}=100 \mathrm{~s}^{-1}\right)$, an error of $100 \%$ in k produces an error of only $4 \%$ in $\Delta G^{*}$, and an error of $6^{\circ} \mathrm{K}$ in the temperature introduces only $2 \%$ error in $\Delta G^{*}$.

The Arrhenius equation (6) may be used to calculate a value

$$
k=A \exp \left(-E_{a} / R T\right)
$$

Eq. (6)

$$
\mathrm{k}=\text { reaction rate constant }
$$

$A=$ pre-exponential factor
$\mathrm{E}_{\mathrm{a}}=$ Arrhenius activation energy
R and T have their usual meaning
of $E_{a}$ from a plot of $1 n k$ vs $1 / T$. It can be shown that the relative error in $\mathrm{E}_{\mathrm{a}}$ is given by Eq. (7): ${ }^{8}$

$$
\left(\sigma_{\mathrm{E}} / \mathrm{E}_{\mathrm{a}} \simeq\left\{\left[2 \mathrm{~T}^{2} /(\Delta \mathrm{T})^{2}\right]\left(\sigma_{\mathrm{T}} / \mathrm{T}\right)^{2}+2[\Delta(\operatorname{lnk})]^{-2}\left(\sigma_{\mathrm{k}} / \mathrm{k}\right)^{2}\right\}^{\frac{1}{2}}\right.
$$

Eq. (7)
where the symbols have their usual meanings. Since Equation (8) is valid for a unimolecular process,

$$
\begin{equation*}
E_{a} \simeq \Delta H^{*} \tag{8}
\end{equation*}
$$

an error introduced in $k$ and $T$ into the calculation of $\Delta H^{*}$ will result in an error in $\Delta H^{*}$ of the same order of magnitude as that associated with $E_{a}$, i.e.:

$$
\begin{equation*}
\sigma_{\mathrm{E}_{\mathrm{a}}} / \mathrm{E}_{\mathrm{a}} \simeq \sigma_{\Delta \mathrm{H}^{*} / \Delta \mathrm{H}^{*}} \tag{9}
\end{equation*}
$$

From Eq. (7), the error in $E_{a}$ introduced by a relative error in $T$ of $1 \%$, for a $20^{\circ}$ (Kelvin) temperature range centered around $200^{\circ} \mathrm{K}$ is approximately $14 \%$. If the temperature range, $\Delta T$, is extended to cover $30^{\circ} \mathrm{K}$, the error in E is reduced to $9 \%$. For an uncertainty of $25 \%$ in the values of $k$ for a range of $k$ values of 2.0 to $60 \mathrm{~s}^{-1}$, the error in $E_{a}$ is approximately $10 \%$. The total error in $E_{a}$ for $\Delta T=30^{\circ} K$ and a range in $k$ of 2 to $60 \mathrm{~s}^{-1}$ is approximately $21 \%$. This is a significant error in $E_{a}$ (and subsequently $\Delta H^{*}$ ) and graphically demonstrates the reason why so many of the values in the literature for $\Delta H^{*}$ (and $\Delta S^{*}$ ) for dynamic organic systems differ markedly. ${ }^{4}$ The total error in $\mathrm{E}_{\mathrm{a}}$ (and $\Delta \mathrm{H}^{*}$ ) may be reduced somewhat by extension of the temperature range, as can be seen from the calculations above. More important, however, is the accurate measurement of the reaction rate constant $k$. To insure the best possible analysis, it is therefore imperative that the line-shape remain sensitive to temperature changes over the entire temperature range. To enhance this sensitivity, Kleier and co-workers ${ }^{57}$ suggested that moderately complex spin-systems may be better candidates for DNMR studies since there are usually present several temperature dependent spectral parameters. For example, there would be several signals and/or coupling constants for visual comparison. Thus, the probability that more than one set
of variables would produce the same spectrum would expectedly be reduced. Since visual comparison of simulated and experimental spectra appears to be the method of choice ${ }^{8}$ for the determination of the rate constant, this may significantly reduce the uncertainty in the rate constant k .

## RESULTS AND DISCUSSION

The large amount of research activity concerning the isolation 79 and synthesis ${ }^{27,31}$ of $\alpha$-methylene- $\gamma$-butyrolactones as possible antitumor agents prompted our investigation of the dynamic characteristics of the spiro- $\alpha$-methylene- $\gamma$-butyrolactone system $56 a \underset{\sim}{\leftarrow} 57$ a. Reported

herein are the first thermodynamic $\left(\Delta G^{o}{ }_{-88}{ }^{\circ} C_{C}=+0.10 \mathrm{kcal} / \mathrm{mol}\right.$; $\left.\Delta H^{\mathrm{O}} \simeq-0.13 \mathrm{kcal} / \mathrm{mol} ; \Delta \mathrm{S}^{\mathrm{O}} \simeq-1.2 \mathrm{eu}\right)$ and kinetic $\left(\Delta \mathrm{G}^{*}{ }_{-55^{\circ} \mathrm{C}}=+10.9\right.$ $\left.\mathrm{kcal} / \mathrm{mol} ; \Delta \mathrm{H}^{*}=+9.6 \mathrm{kcal} / \mathrm{mol} ; \Delta \mathrm{S}^{*} \simeq-5.9 \mathrm{eu}\right)$ parameters associated with ring reversal of such a system although there is known antitumor activity associated with such a spiro lactone. ${ }^{82}$ Also reported are the syntheses, NMR $\left({ }^{1} H\right.$ and $\left.{ }^{13} C\right)$, IR and physical characteristics for a series of analogous substituted compounds. In addition, an analysis of possible solvent effects displayed in the NMR spectra of several of these compounds is presented. A single crystal X-ray analysis of compound 56 b is also reported; this allowed unequivocal assignment of the stereochemistry for this solid isomer and aided in the assignment of resonances in the NMR spectra of these compounds.

Although a variety of techniques are available for the synthesis of $\alpha$-methylene- $\gamma$-butyrolactones, ${ }^{27,31}$ the method outlined below ${ }^{80}$ was chosen for its simplicity and adaptability to the synthesis of the compounds $\underset{\sim}{56 a-56 e}$ and $57 a-57 e$ necessary for subsequent DNMR studies. In all cases, the Reformatsky reaction was employed under identical conditions for reaction with an appropriate cyclohexanone. Addition of each reaction mixture to $\mathrm{H}_{2} \mathrm{SO}_{4}$ at $0^{\circ} \mathrm{C}$ yielded either an oil or a crystalline product which was extracted with ether. However, careful recovery of the crude product, followed by purification either by distillation or recrystallization, gave, upon cooling, a crystalline material for each compound except $56 \underset{\sim}{*} 57 \mathrm{e}$. The physical and synthetic data are reported in Table I for the various compounds synthesized.

Spectral data from the ${ }^{1}{ }_{H}$ NMR (Plates I-XIII) and IR (Plates XIVXVIII) for each of the compounds 56a-56e and 57a-57e are given in Table II. Although the synthesis of compound $56 \mathrm{a} \underset{\sim}{57 a}$ was previously reported, 75,82 only an oil was obtained which was undoubtedly due to the attempted purification via distillation which resulted in partial decomposition. ${ }^{82}$ It is also highly probable that some polymerization occurred in the distillation as well. In our hands, only $56 e \stackrel{\rightarrow}{\leftarrow} \underset{\sim}{\sim}$ has not as yet yielded a crystalline product upon cooling a solution of the oil in commercial hexanes (bp $67^{\circ}-71^{\circ} \mathrm{C}$ ). Distillation of $56 \mathrm{e} \underset{\sim}{\leftarrow} 57$ yielded a contaminated product which partially polymerized even in the dark and when refrigerated.

Ethy1 $\alpha$-(bromomethyl)acrylate (24) was initially synthesized via a published method. ${ }^{21}$ However, it was later shown that careful control of the reaction conditions can greatly improve the yield while eliminating a step. ${ }^{81}$

$\mathrm{c}_{\text {Four }}$ line portion of AMXY pattern.
${ }^{\mathrm{d}}$ Spectrum showed gross impurities.

Compound 58 c was synthesized from diketone 61 using a modified procedure of Frank and $\mathrm{Ha}^{24}$ as outlined below (see Experimental). The overall yield of 3,3-dimethylcyclohexanone (58c) was $17 \%$.

Compound 58 e was synthesized by a minor modification of the method of Coates and Sowerby ${ }^{11}$ from cyclohexanone (58a) as outlined below (see Experimental). The overall yield of 2,2-dimethylcyclohexanone ( $\underbrace{58 e}_{\sim}$ ) was $14 \%$.

Compounds 56 and 57 are interconvertable conformers. At temperatures below $198^{\circ} \mathrm{K}\left(-75^{\circ} \mathrm{C}\right)$, the frequency of interconversion between these two conformers is sufficiently slow that signals for each conformer are distinguishable in the low temperature ${ }^{1} H$ NMR spectra, i.e., 55,87

$$

$\nu_{\mathrm{a}}=$ the chemical shift of $\mathrm{H}(4)$ in 56 a
$\nu_{e}=$ the chemical shift of $H(4)$ in $57 a$

58 a

Under these conditions, both conformers are easily detected, and the relative peak areas can be measured by integration. In this particular case, 56 a and 57 a gave rise to two separate, three-1ine spin patterns ( $\mathrm{X}_{2}$ of an $\mathrm{AMX}_{2}$ pattern) between $177^{\circ} \mathrm{K}$ and $185^{\circ} \mathrm{K}$ which was below the compound's coalesence temperature ( $\mathrm{T}_{\mathrm{c}}$ ) of $209^{\circ} \mathrm{K}\left(-64^{\circ} \mathrm{C}\right)$. The two concentrations used were 0.024 M and 0.036 M solutions in acetone- $\mathrm{d}_{6}$. A representative partial spectrum of a solution ( 0.036 M ) of $56 \mathrm{a} \underset{\sim}{~ 57 a ~}$ is shown in Figure 1. The equilibrium constant for the ring reversal can be determined from the relative areas and, using these values, calculation of $\Delta G^{o}$ follows:

Figure 1. Spectrum of $56 \mathrm{a} \stackrel{\vec{\leftarrow}}{\leftarrow} 57 \mathrm{a}, 177^{\circ} \mathrm{K}, 0.036 \mathrm{M}$ in Acetone-d ${ }_{6}$. Sweep Width $=100 \mathrm{~Hz}$, Offset $=230 \mathrm{~Hz}$ (PFT)

$$
\Delta G^{0}=-R T \ln ([57 a] /[56 a])
$$

[56a] = area under peak corresponding to conformer 56a. [57a] = area under peak corresponding to conformer 57a.

Values for $\Delta G^{\circ}$ at various temperatures for the two different concentrations are given in Table III. Qualitative values for $\Delta H^{\circ}$ are also given. However, the very narrow temperature range accessible, because of solubility limitations in the determination of $\mathrm{K}_{\mathrm{eq}}$ (as we11 as the very small change in $\mathrm{K}_{\mathrm{eq}}$ over this temperature range) does not permit extremely acurate $\Delta H^{\circ}$ values to be obtained (see Error Analysis in the Historical). The values of $\Delta \mathrm{H}^{\circ}$ at the different concentrations were calculated to permit relative comparisons between this method of evaluating $\Delta G^{\circ}$ and the chemical shift method ${ }^{16}$ also used in this study. Calculations of $\Delta H^{\circ}$ were done by a least-squares analysis of the plot of $\ln K_{\text {eq }}$ vs $1 / T$ using a programmable, hand calculator (Hewlett-Packard model 25) (see Figure 5, page 100). The values for $\Delta G^{\circ}$ in Table III clearly show that the conformer corresponding to the upfield signal in the low temperature NMR spectra of this equilibrating system is favored thermodynamically by a modest amount.

Previous work recorded in the literature ${ }^{50}$ suggested that steric compression due to typical 1,3-interactions with protons on the cyc1ohexyl ring would cause proton signals to be shifted to lower field for axially situated methylene groups. Based on these observations, we initially concluded that structure 56 represented the predominant conformer in our system. In order to establish unequivocally the

| :--- | :---: | :---: | :---: |
|  | 177 | $0.811 \pm 0.019$ | $\Delta H^{\mathrm{o}}(\mathrm{kcal} / \mathrm{mol})^{\mathrm{b}}$ |

${ }^{\text {a }}$ Samples were prepared in acetone- $\mathbf{d}_{6}$ with TMS as an internal standard.
${ }^{\mathrm{b}} \Delta \mathrm{H}^{\mathrm{O}}$ was calculated by a least-squares fit of $\ln \mathrm{K}_{\mathrm{eq}} \underline{\mathrm{vs}} 1 / \mathrm{T}$ using average values of $\mathrm{K}_{\mathrm{eq}}$.
conformer in predominance, compounds 56 b and $57 b$ were synthesized and isolated as shown above. Separation of the two isomers was achieved by column chromatography over Florisil. The compound isolated in predominance was submitted for X -ray analysis and was determined to be 56b. Independent NMR analysis of both isomers in solution showed distinctly that protons of the methylene group at $C(4)$ in 56 b resonate at higher field ( $\delta 2.74$ ) than the analogous protons in 57 b ( $\delta 2.85$ ) (see page 35).

Although the low temperature method of integrated areas is the most theoretically satisfying technique for determining the equilibrium constant and for subsequent calculation of $\Delta G^{\circ}$, it suffers from several limitations in this case. It was difficult to maintain constant probe temperatures below the coalesence temperature $T_{c}$ for extended periods of time. The range of temperature in which determinations could be made was governed by the coalesence process and by the freezing point of the solvent. The compound 56 a . $\vec{\leftarrow} 57 \mathrm{a}$ proved to be insoluble at low temperatures in $\mathrm{CS}_{2}, \mathrm{H}_{2} \mathrm{CCl}_{2}, \mathrm{HOCH}_{3}$ and cyclohexane. No other solvents were tried. While the values obtained for $\Delta G^{0}$ for 56 a $\vec{\leftarrow} 57$ a are of good accuracy, one cannot assume that they represent the equilibrium at higher temperatures, especially in view of the rather high value estimated for $\Delta H^{\circ}$.

The chemical shift method of determining the equilibrium constant ${ }^{16}$ was used to obtain values for $\Delta G^{\circ}$ at temperatures above $T_{c}$ for which $k_{r}$ (reaction rate constant) has the following relationship to $\nu_{a}$ and $\nu_{e}:$

$$
k_{r} \ll \pi\left[\nu_{a} \nu_{e}\right] / \sqrt{2}
$$

Under these conditions of frequent exchange, a mobil system will give rise to only one signal in the NMR spectrum for protons previously affected by the reversal process under conditions of "slow" or infrequent exchange. The chemical shift of this signal will result from a time averaging of the independent signals for the individual conformers, weighted by the mean lifetime of the mobil system in each conformational orientation. ${ }^{8}$ The equilibrium constant can therefore be calculated by:

$$
\mathrm{K}_{\mathrm{eq}}=\left(\delta_{\mathrm{a}}-\delta\right) /\left(\delta-\delta_{e}\right)
$$

$$
\begin{aligned}
\delta_{a} & =\text { shift of } H_{a}(4) \text { for pure conformer } 57 a \\
\delta_{e} & =\text { shift of } H_{e}(4) \text { for pure conformer } 56 a \\
\delta & =\text { time average shift of } 56 a \nrightarrow 57 a
\end{aligned}
$$

Since $\delta_{a}$ and $\delta_{e}$ were not available above $T_{c}$ in mobile systems, these values were evaluated from the shift of the conformationally locked t-butyl-substituted compounds 56 b and 57 b . Average shifts obtained at each temperature are given in Table IV. The results of this method of determining $K_{e q}$ as well as $\Delta G^{0}$ (and $\Delta H^{\circ}$-see Figure 6, page 101) are shown in Table V. Again, the positive values of $\Delta G^{0}$ indicate the conformational preference of 56 over 57 . The magnitudes of the values for $\Delta G^{0}$ are greater from this method of calculation by a factor of three than those values obtained by the low temperature area method. However, values for $\Delta G^{0}$ for the lower temperatures may be calculated from the higher temperature shift data using the thermodynamic relationship shown;

$$
\Delta G^{0}=\Delta H^{\circ}-T \Delta S^{\circ}
$$

one can, of course, also calculate $\Delta H^{\circ}$ and $\Delta S^{\circ}$. Comparison of the

${ }^{\mathrm{d}}$ Values calculated from integrated areas (Table III).
${ }^{\mathrm{e}}$ Values extrapolated from chemical shift data.
extrapolated values with actual values calculated at low temperatures by the use of integrated areas (lable V) shows good agreement. A plot of $\ln K_{\text {eq }}$ vs $1 / T$ (see Figure 8 , page 103) of the combined integrated area and chemical shift data gave a "best" value for $\Delta H^{\circ}$ of $-0.133 \pm$ $0.04 \mathrm{kcal} / \mathrm{mol}$ and a "best" value of $\Delta \mathrm{S}^{\mathrm{O}}$ of ca. -1.2 eu.

To investigate the kinetics of the ring reversal, a study of the NMR spectra of the mobil system $56 \mathrm{a} \vec{\sim} 57 \mathrm{a}$ was undertaken using complete line-shape analysis (L.S.A.)..$^{8}$ The $56 \stackrel{\rightharpoonup}{\leftarrow} 57$ a system was particularly suited to this type of evaluation because the spiro ring junction effectively isolates the five-membered ring of the lactone from the sixmembered ring. This reduces the spectral pattern of the protons in the lactone ring to a first-order $\mathrm{AMX}_{2}$ pattern which can be simulated by a DNMR3 program. ${ }^{56}$ Because of the extensive $H-H$ coupling in the spectrum, as well as the need to evaluate the rate constant over a range of temperatures, the approximate equations ${ }^{58}$ which were derived from lineshape theory were not deemed feasible.

The chemical shifts and coupling constants used in the analysis were extrapolated to higher temperatures assuming a linear relationship. Values for the transverse relaxation time ( $T_{2}$ ) were estimated by measuring the width at half height of the TMS internal standard. The values used as the input parameters for the line-shape analysis are given for each temperature in Table VI.

Visual comparison of the simulated spectra with the experimental spectra was used to assess the closeness of the fit. Estimates of the deviations in the rate constant were also done in this fashion. The results of the simulations are shown in Figure 2 and in Plates

 Samples Were Prepared as 0.024 M Solutions in Acetone-d 6 with TMS as an Internal Standard

XIX-XXVI and the calculated activation parameters are tabulated in Table VII.

Side bands resulting from a large solvent peak (upfield) is noticeable in the experimental spectrum obtained at $201^{\circ} \mathrm{K}$ as shown in Figure 2. Repeated attempts failed to remove this interference at this temperature. However, the side bands were minor or did not exist at the other temperatures used in this investigation.

It is interesting that values from the literature 26,84 for $\Delta G^{*}$ in simple and $1,1-$ disubstituted cyclohexyl systems are in close agreement with our values for the various temperatures investigated. A comparison of published values for $\Delta S^{*}$ and $\Delta H^{*}$ for the simple systems with those found for $56 \mathrm{a} \underset{\sim}{\leftarrow} 57$ is difficult since there appears to be large discrepancies in the magnitudes of these parameters even in simple systems. For example, values for $\Delta S^{*}$ ranging from +4.9 to 5.8 eu have been recorded for cyclohexane itself. ${ }^{4}$ In regard, it is known that errors in $\Delta H^{*}$ and $\Delta S^{*}$ are coupled (due to the methods used to calculate them) so that high $\Delta H^{*}$ values correspond to low $\Delta S^{*}$ values and vice versa. ${ }^{8}$ While it has been suggested that extension of the temperature range would reduce the error in $\Delta H^{*}$ and $\Delta S^{*}$, the spectra must remain reasonably sensitive to changes in the rate constant at the extremes of this range. ${ }^{8}$ We did not detect any significant change in the spectrum for our system above $235^{\circ} \mathrm{K}\left(-38^{\circ} \mathrm{C}\right)$.

It was found that the five-membered lactone ring is puckered in the solid state. Indeed, even though the molecule 56 b does not possess an asymmetric carbon, it crystallizes in the non-centrosymmetric space group $P 2_{1} 2_{1} 2_{1}$ due to selective crystallization of the puckered forms.

## ACTIVATION PARAMETERS CALCULATED FROM LINE-SHAPE ANALYSIS FOR $56 \mathrm{a} \stackrel{77 a^{a}}{ }$

|  | $+9.60 \pm 1.3$ |  |  |

a Samples were prepared as 0.024 M solutions in acetone- $-_{6}$ with TMS as
as an internal standard.
${ }^{\mathrm{b}} \Delta \mathrm{H}^{*}$ and $\Delta \mathrm{S}{ }^{*}$ were calculated from a least squares fit of $\ln \left(k_{r} / \mathrm{T}\right)$ vs
$1 / \mathrm{T}, \mathrm{r}^{2}=0.998$ (see Figure 7 , page 102 ).

Although the mirror image of this form would be expected to be of equal energy, the space requirements of a disordered lactone would be too great to allow both conformers of the puckered ring to exist together in a disordered crystal structure.

In solution, the barrier to interconversion of the five-membered ring between two conformers must be very small. One can see from the NMR data in Table II for the 7,7-dimethyl analogue $56 \mathrm{c} \stackrel{\vec{c}}{\leftarrow} 57 \mathrm{c}$ that this interconversion may be biased indirectly by destruction of the symmetry of the system owing to increased 1,3-interactions experienced by the five membered ring. This results in nonequivalence of the $H(4)$ protons. This symmetry of interaction is restored in the 7,7,9,9-tetramethyl substituted analogue $56 \mathrm{~d} \underset{\sim}{\leftrightarrows} 57 \mathrm{~d}$ resulting in the familiar $\mathrm{AMX}_{2}$ pattern for the lactone ring protons (see Plates X and XI ). The interconversion (or "breathing motion") of the five-membered ring must occur in solution simultaneously with the six-membered reversal process. Although not strictly analogous, the barrier for the pseudorotation between puckered forms of cyclopentanone has been determined to be between 2.1 and $3.7 \mathrm{kcal} / \mathrm{mol} .^{12}$ This corresponds to a rate of reversal (assuming small $\Delta \mathrm{S}^{*}$ ) at $190^{\circ} \mathrm{K}$ of $2.2 \times 10^{8}$ to $1.5 \times 10^{10} \mathrm{~s}^{-1}$. Thus, it would seem to be much too rapid to be detectable via NMR methods. However, if the NMR spectrum is sensitive to changes induced by this process, the possibility of the breathing motion affecting the magnetic field around certain nuclei in the spectrum cannot be eliminated and may be a source of error, especially at the lower temperatures. However, this process would not be expected to interfere with evaluation

of the thermodynamic parameters, assuming that this motion in the fivemembered ring does not impart any dissymmetric operation preferentially on either of the six-membered conformers.

As mentioned previously, several studies in the past have cast doubt on the validity of the chemical shift method in the evaluation of an equilibrium constant. $6,47,48$ Jensen and Beck 47 showed evidence suggesting that the chemical shift method, as originally applied by Eliel, ${ }^{16}$ was invalid. Free energy values (reported as $A=-\Delta G^{\circ}$ for an equilibrium defined as axial $\underset{\leftarrow}{ }$ equatorial) for several mono-substituted cyclohexanes obtained by the shift method at $\sim 25^{\circ} \mathrm{C}$ were compared directly with A values obtained at very low temperatures ( $<-80^{\circ} \mathrm{C}$ ) from integrated areas. As mentioned previously (see Historical), a correction was applied to the chemical shift method based on the shift difference observed at low temperatures; the values thus derived at $\sim 25^{\circ} \mathrm{C}$ were also compared to the values calculated by integrated areas. It was noted by Jensen and Beck that the "corrected" values in all cases were
much closer to the values obtained by integrated areas than those obtained by the "uncorrected" method. However, this inherently assumes that the $\Delta \mathrm{S}^{\mathrm{o}}$ for the equilibrium over a temperature range $>100^{\circ} \mathrm{C}$ is ca. 0.0 eu. As will be demonstrated later, this is not necessarily the case. Jensen and Beck ${ }^{47}$ report only one complete set of chemical shifts at a temperature other than $\sim 25^{\circ} \mathrm{C}$. The complete set of values for bromocyclohexane ( $31 \underset{\sim}{\star}$ 32) are reproduced in Table VIII. For a temperature of $+24^{\circ} \mathrm{C}$ the "corrected" value of $\Delta G^{\circ}(-0.55 \mathrm{kcal} / \mathrm{mol})$ compared well with the value obtained by integrated areas at $-84^{\circ} \mathrm{C}$ (- $0.49 \mathrm{kcal} / \mathrm{mol}$ ) if one assumed a negligible change for $\Delta \mathrm{S}^{\circ}$. The "uncorrected" value for $\Delta G^{\circ}$ at $25^{\circ} \mathrm{C}$ was given as $-0.35 \mathrm{kcal} / \mathrm{mol} .^{47}$ At $\sim-48^{\circ} \mathrm{C}$, we obtain a completely different result. The "corrected" value, calculated from the data given by Jensen and Beck ${ }^{47}$ using the method which they outlined, was $-0.76 \mathrm{kcal} / \mathrm{mol}$ and the "uncorrected" value (calculated directly from the data) was $-0.55 \mathrm{kcal} / \mathrm{mol}$. Clearly, if the "corrected" method is valid, one should be able to calculate intermediate values of $\Delta G^{\circ}$ which also compare favorably with those obtained by the integrated area method at very low temperatures. In this case, the value of $\Delta G^{\circ}\left(-0.76 \mathrm{kcal} / \mathrm{mol}\right.$ at $\left.-48^{\circ} \mathrm{C}\right)$ calculated for an intermediate temperature does not correlated well with the integrated area value. This fact, coupled with the comparative improvement in the $\Delta G^{\circ}$ value ( $-0.55 \mathrm{kcal} / \mathrm{mol}$ at $-48^{\circ} \mathrm{C}$ ) calculated by the "uncorrected" method (same temperature), suggests that many careful variable temperature studies are needed before either method can be accepted unequivocally.

A comparison of the "corrected" and "uncorrected" chemical shift methods for $56 \mathrm{a} \underset{\sim}{57}$ a is shown in Table IX. The correction values were

${ }^{e}$ Shift methods are not applicable.
determined at the low temperature ( $<-190^{\circ} \mathrm{K}$ ) and applied to the shift values as given in Table IV. It is evident that if one considers only one temperature, e.g. $286.5^{\circ} \mathrm{K}\left(13^{\circ} \mathrm{C}\right)$, the "corrected" values calculated by the method of Jensen and Beck ${ }^{47}$ would compare favorably with those values obtained at low temperatures (Table III). However, if one considers the temperature dependence of the equilibrium constant (and ultimately the value of $\Delta S^{0}$ ), the method of Jensen and Beck shows a progressively larger deviation at lower temperatures from the integrated area values, whereas the original chemical shift method proposed by Elie1 ${ }^{16}$ shows a progressively smaller deviation. Also, as seen in Table V, values obtained by extrapolation to lower temperatures for the method of Eliel gives values in very good agreement with those obtained at low temperature. It should be emphasized that in bromocyclohexane the data is very meager and no attempt is made here to discredit either method. On the contrary, it is our opinion that each case must be judged on its individual characteristics, and that all methods must be compared carefully over an extended temperature range.

The $H(4)$ protons for $56 \mathrm{a} \stackrel{\rightharpoonup}{\leftarrow} 57 \mathrm{a}, 56 \mathrm{~b}$, and 57 b are insulated from the six-membered ring by a carbon atom. It has been observed ${ }^{18,22}$ that this insulation could reduce the influence of distortion in the six-membered ring due to the t-butyl group in the determination of $\Delta G^{\circ}$. In addition, the X-ray analysis of 56 b shows that distortion in the cyclohexyl system due to the spiro ring junction is greater than the distortions due to the t-butyl group. This can best be seen by comparison of the tortion angles listed in Table X. Angles C(9)-C(10)-$C(5)-C(6)$ and $C(10)-C(5)-C(6)-C(7)$ clearly show a deviation at the spiro end from the normal value of $57^{\circ}$ for cyclohexane 28,63 by

TABLE X

| $C(5)-0(1)-C(2)-C(3)$ | $8.9^{\circ}$ | $C(9)-C(10)-C(5)-C(6)$ | $-49.5^{\circ}$ |
|  |  | $C(10)-C(5)-C(6)-C(7)$ | $48.8^{\circ}$ |

$7.6^{\circ}$ and $8.2^{\circ}$, respectively. Angles $C(6)-C(7)-C(8)-C(9)-C(10)$ show a deviation at the t-buty1 end of $2.4^{\circ}$ and $3.4^{\circ}$, respectively. These value, of course, cannot be extrapolated directly to a solution of 56 b . However, studies of a few simple and substituted cyclohexanes as well as a variety of pentamethylene heterocycles in solution ${ }^{63}$ have shown agreement with $X$-ray data of such parameters within $\pm 2^{\circ}$. This suggests that structural changes for such systems upon dissolution are small. Hence, it would be expected that chemical shift differences between biased and unbiased systems in solution due to the t-butyl group would be small relative to the effects at the spiro part of the molecule. The agreement of the extrapolated values in Table V with those values obtained by integrated areas clearly supports this contention.

As stated previously, the thermodynamic parameter $\Delta G^{\circ}$ calculated displays a small but distinct conformational preference for the conformer 56a (C-0 bond axial). Values in the literature for similar spiro dioxolane systems ${ }^{89}$ have yielded comparable results for $\Delta G^{\circ}$ at low temperatures. The $\Delta G^{\circ}$ values obtained at higher temperatures are consistent with those obtained at low temperatures, if one assumes a value of -1.5 eu to be representative for $\Delta \mathrm{S}^{\circ}$. This value is not unreasonable when compared to published values obtained for the entropy change favoring, for example, the less assqciated $0 H$ group in the axial conformer of 3,3,5-trimethylcyclohexanol in strongly associating solvents. ${ }^{17}$ It has also been shown that aprotic, polar solvents can strongly influence the position of an equilibrium when there exists a possible preferential solvation effect for one of the isomers. ${ }^{22}$

In order to qualitatively assess the affects of solvation in the equilibrium, each of the spiro lactones in this study was subjected to $1_{H}$ NMR analysis in acetone- ${\underset{-}{6}}$ and $\mathrm{CCl}_{4}$ (or $\mathrm{DCCl}_{3}$ when FT-NMR was necessary due to limited quantities of the compound). The results of these comparative studies are given in Table XI.

Careful inspection of Table XI reveals some extremely interesting features. Comparison of the chemical shift of the $56[\mathrm{H}(4)] \underset{\sim}{57}[\mathrm{H}(4)]$ for the $56 \mathrm{a} \stackrel{\rightharpoonup}{\leftarrow} 57 \mathrm{a}$ system with those in $56 \mathrm{~b}[\mathrm{H}(4)]$ and $57 \mathrm{~b}[\mathrm{H}(4)]$ systems

in $\mathrm{DCCl}_{3}$ shows that the shift in $56 \mathrm{a} \underset{\sim}{\rightarrow} 57 \mathrm{a}(\delta 2.71)$ is closer to the shift for $57 b$ ( $\delta 2.74$ ) than for $56 b(\delta 2.65)$. This suggests that in $\mathrm{DCCl}_{3}$ the position of the equilibrium is reversed from that observed in acetone $-{\underset{6}{6}}^{6}$. That is to say, in $\mathrm{DCCl}_{3}$ conformer 57 a is favored $\left(\Delta G^{0} \simeq-0.4 \mathrm{kcal} / \mathrm{mol}\right)$, while in acetone- $-_{6} 56 \mathrm{a}$ is favored $\left(\Delta G^{0} \simeq 0.2\right.$ $\mathrm{kcal} / \mathrm{mol}$ ). Low temperature measurements of the equilibrium constant by integrated areas, which support the chemical shift findings in acetone- $-_{6}$, unfortunately could not be done in $\mathrm{DCCl}_{3}$ because of the high melting point of this solvent $\left(-63^{\circ} \mathrm{C}\right)$ and the very low solubility of $56 \mathrm{a} \stackrel{\rightharpoonup}{\leftarrow}$ 57a.

This same type of startling reversal was also observed by Uebel and co-workers ${ }^{89}$ for 2,2-dimethyl-1,3-dioxaspiro[4.5]decane

$42 \mathrm{~b} \stackrel{+}{ }{ }^{\star} 3 \mathrm{~b}$. Severai other similar 1,3-dioxaspiro[4.5]decanes were also examined in this work. ${ }^{89}$ of all the systems studied, only
 and integrated area ( $\Delta_{G}{ }^{\circ}=00.13 \mathrm{kcal} / \mathrm{mol}$ ) analysis a conformational preference for the conformer with the $\mathrm{C}-0$ bond in the equatorial position(43b). The investigation of $42 \mathrm{~b} \stackrel{43 \mathrm{~b}}{ }$ was done in a $1: 9$ mixture of $\mathrm{D}_{3} \mathrm{COD}: \mathrm{DCCl}_{3}$ for the chemical shift measurements and in a $1: 1$ mixture of $\mathrm{D}_{3} \mathrm{COD}: \mathrm{DCCl}_{3}$ for the integrated area method. All of the other experiments reported by Uebel and co-workers ${ }^{89}$ on the other similar spiro dioxolanes were done in acetone-d ${ }_{6}{ }^{\circ}$

Some type of differential solvent effect must be present in the $56 \mathrm{a} \rightarrow 57$ a equilibrium. Ford and Allinger, ${ }^{22}$ in a study of solvent effects of the carbethoxycyclohexane system ( $\underset{\sim}{66} \underset{\sim}{67}$ ), postulated that

the axial conformer $\underset{\sim}{66}$ would occupy a smaller molar volume than $\underset{\sim}{67}$ and therefore would be favored due to the exertion of internal solvent pressure. 76 The latter would be greater in polar solvents than in nonpolar solvents. It is difficult to predict which conformer in the $56 \mathrm{a} \not \underset{\sim}{ } 57 \mathrm{a}$ system would have a larger molar volume and even more difficult to rationalize by this argument alone the apparent complete reversal of the conformational preference. Eliel and Gilbert ${ }^{17}$ have shown that the magnitudes of $\Delta H^{O}$ and $\Delta S^{O}$ for the equilibrium of cis and trans-butylcyclohexanol are very dependent upon the association properties of the solvent. However, no drastic changes in conformational preferences were observed. While there is evidence in the literature $20,41,42,53$ that chloroform can associate to some extent with many proton acceptors (e.g. acetone $20,41,42$ and diethyl ether 20,41 ) it would be very difficult to determine how this interaction could result in a reversal of the conformational preference in the $\underbrace{56 a} \underset{\sim}{57 a}$ system.

It is clear from the shift differences between $\mathrm{CC1}_{4}$ and $\mathrm{DCC1}_{3}$ for protons $56 \mathrm{a}[\mathrm{H}(4)] \stackrel{\rightharpoonup}{\leftarrow} 57 \mathrm{a}[\mathrm{H}(4)]$ that $\mathrm{DCCl}_{3}$ in some manner solvates the system different from that in acetone $-d_{6}$. Hydrogen bonding of the deuterium with either or both of the oxygens seems very probable. Indeed, evidence from both $\operatorname{IR}^{20}$ and $\operatorname{NMR}^{20,41,42,53}$ analysis strongly suggests that hydrogen bonding between $\mathrm{HCCl}_{3}$ and acetone exists to a considerable extent. The deshielding of protons $H\left(3^{\prime} a\right), H\left(3^{\prime} b\right)$ and $H(4)$ in the $56 \mathrm{a} \underset{\sim}{\leftarrow} 57 \mathrm{a}$ system (as evidence by the down field shifts for these proton signals in $\mathrm{DCCl}_{3}$ compared to $\mathrm{CCl}_{4}$ ) could result from a net increase in the polarization of the lactone ring due to this hydrogen bonding. ${ }^{77}$ This assumes the dipole is directed parallel to

570

Shift Differences $\left(\mathrm{DCCl}_{3}-\mathrm{CC1}_{4}\right)$

the carbonyl bond and hydrogen bonding (with $\mathrm{DCC1}_{3}$ ) could reduce the charge density of the lactone ring. If differential solvation of one of the conformers occurs in the $56 \mathrm{a} \underset{\sim}{~} 57$ a system, one might expect that solvation effects would be dissymmetric with respect to the plane of the six-membered ring. In order to investigate this possibility, the spectra of the gem-substituted homologs $56 \mathrm{c} \vec{\leftarrow} 57 \mathrm{c}$ and $56 \mathrm{e} \stackrel{\rightharpoonup}{\leftarrow} 57 \mathrm{e}$ were examined. Conceivably the 7,7 -dimethyl proton signal of $56 \mathrm{c} \xrightarrow{〔} 57 \mathrm{c}$ might be used to evaluate this hypothesis. It is immediately evident as shown below that only one of the methyl groups in $56 \mathrm{c} \underset{\sim}{5} \underset{\sim}{c}$ displays a solvent shift $(\Delta \delta)$ in acetone $-\mathbb{d}_{6}$ compared to the situation in $\mathrm{CCl}_{4}$. The 6,6 -dimethyl proton signals in $56 \mathrm{e} \underset{\leftarrow}{ } 57 \mathrm{e}$ whow a somewhat different behavior. Again, one of the proton signals for one methyl group is shifted upfield $(-4 \mathrm{~Hz})$, but the proton signal for the other geminal group is shifted downfield $(+2 \mathrm{~Hz})$. This would seem to indicate that

*tentative assignment of cis-, (c) and trans-, (t)
one of the methyl groups in the $56 c \rightarrow 57 c$ equilibrium is within the anisotropic influence of the solvating acetone-d $d_{6}$. The lack of a large shift difference for the other methyl group ( ${ }^{1} \mathrm{H}$ signals) suggests that this methyl lies outside the anisotropic influence of the acetone $-_{6}$ which may be aligned with the dipole of the lactone ring. Results similar to this are also observed for the $5 \underset{\sim}{56 \mathrm{~d}} \underset{\sim}{57 \mathrm{~d}}$ system; however, the nature of the strong 1,3,5-interactions in this case makes the use of this compound as a model of somewhat dubious value. Nevertheless, some general conclusions can be drawn from these results. Solvation is acetone- $d_{6}$ most probably occurs in a dissymmetric fashion across the plane of the six-membered ring (note $56 \mathrm{c} \underset{\sim}{57 c}$; see above). and these solvation effects in acetone- $\underline{d}_{6}$ can be detected for methyl protons situated in a cis or trans arrangement to the $\mathrm{C}-\mathrm{O}$ bond in the

$$

five-membered ring (note $56 \mathrm{e} \underset{\sim}{\vec{*}} 57 \mathrm{e}$ ). Proposed solvent orientations for the two different solvents are given below based upon parallel $(\underset{\sim}{68} \underset{\sim}{69}, 70 \underset{\sim}{71}$ and $72 \underset{\sim}{*} 73$ ) and anti-parallel ( $74 \underset{\sim}{*} 75$ ) alignment of the solute-solvent dipoles. Of the four proposed interactions suggested, the $74 \underset{\sim}{\underset{\sim}{~}} 75$ antiparallel interaction seems unlikely. In our opinion, the relatively high dielectric constant $(\varepsilon=20.5)^{71}$ of acetone would disfavor this type of alignment. ${ }^{72}$ Both $\underset{\sim}{68} \underset{\sim}{*} \underset{\sim}{69}$ and $70 \rightarrow \underset{\sim}{71}$ could be expected to be favored in this type of polar medium, and neither situation can be ruled out. The steric bulk of the methyl groups in acetone $-\frac{d}{6}$ might be situated such that an increase in the 1,3-type interactions for conformer $\underset{\sim}{69}$ could be manifested as shown. This could lead to a favoring of conformer 68 in acetone- $d_{6}$ as observed. However, if one assumes that the steric requirements of the nonbonding electron pairs on $0(1)$ are less than that of $C(4)$ (see page 69), then the relative lack of steric interference evident in

68
69

70
71

72

$\underset{\sim}{70} 71$ could also explain the observed preference for the conformer with the $\mathrm{C}-0$ bond in the axial position.

A possible hydrogen-bond type of interaction of $\mathrm{DCC1}_{3}$ with the lactone could result in associations shown in $72 \underset{\sim}{\leftarrow} 73$. Although the carbonyl oxygen is probably the site of primary solvation, interactions with the nonbonding electron pairs on $0(1)$ must also be considered (as shown in $72 \vec{\sim} 73$ ). Such interactions could lead to a conformation preference for the more easily solvated conformer 73 in which $0(1)$ is equatorially situated.

INDO calculations based upon the positional parameters obtained from a single-crystal X-ray analysis of 56 b predicts a dipole moment of 4.8 D . The resultant vector is most probably directed across the lactone ring towards the carbonyl oxygen (76). This approximation is in good agreement with the observed dipole moment of 3.82 D for $\gamma$-butyrolactone. 68 The direction and position of the dipole vector as shown in $7 \underset{\sim}{7}$ was deduced by assuming the vector of the dipole passes through the center of the negative and positive charges for the lactone ring. These centers were calculated from the partial

76
charges shown in 76 , also obtained from the INDO calculations. This strong dipole moment supports the possibility of both dipole-dipole and hydrogen bond-1ike interactions as postulated above.

The ${ }^{13}$ C NMR of compounds (56a-56d and $\left.57 a-57 d\right)$ were recorded in $\mathrm{DCCl}_{3}$ and the shifts have been given in Table XII. Assignments of shifts were made on the basis of selected model compounds and offresonance ${ }^{1}{ }_{H}$ decoupled spectra. Since substitution of the six-membered ring results in shift differences for the ring carbons, little information can be gleaned from these shift values. Hence, these shifts are not discussed below, but are given in Table XII. The carbon

signals for the lactone ring, however, would be expected to be influenced by the substitution of the six-membered ring perhaps in a subtle and indirect fashion. As can be seen from Table XII, the chemical shift of $C(3)$ remains fairly constant in the series. A similar consistency is present in the shifts of $C\left(3^{\prime}\right)$. The shift variation ( $\Delta v$ ) observed for $C(2)$ is no greater than 3 Hz over the entire series except for 57 b . For example, the shift of $\mathrm{C}(2)$ in 57 b ( 4192 Hz from TMS) is $\Delta \nu=-80 \mathrm{~Hz}$ from the shift for $\mathrm{C}(2)$ in $5 \underbrace{56 \mathrm{a}} \underset{\sim}{57 \mathrm{a}}$ ( 4272 Hz from TMS), while C(2) in 56 b ( 4275 Hz from TMS) differs from the $56 \mathrm{a} \underset{\sim}{〔} \underset{\sim}{\mathrm{~F}} \mathrm{C}(2)$ signal by $\Delta v=+3 \mathrm{~Hz}$. If the chemical shift method is applied to these signals, a value of 0.0375 is calculated for $K_{e q}$, suggesting 56a is heavily favored. When the method is applied to the C(4) signals in the $56 \mathrm{a} \nmid 57 \mathrm{a}, 56 \mathrm{~b}$ and 57 b systems, a value of 0.5 is calculated for $\mathrm{K}_{\mathrm{eq}}$, again suggesting that 56 is favored. Clearly, the shift method as applied to ${ }^{13}$ C shifts must be treated with caution and cannot be as yet universally accepted.

## Single Crystal Analysis of 56b

The numbering scheme and bond distances are shown in Figure 3, and bond angles in Figure 4. The structure consists of a six-membered ring in the chair conformation, a spiro-fused, $\alpha, \beta$-unsaturated $\gamma$-lactone and an anchoring t-butyl group. The chair conformation of the sixmembered ring is significantly flattened near the spiro carbon atom as can be seen from the torsion angles reported in Table X . This is most 1ikely due to a 1,3,5-interaction involving the axial $\mathrm{C}-0$ bond attached to the spiro carbon atom since all other axial positions are occupied

Figure 3. Bond Distances and Numbering Scheme for 56b. Estimated. Standard Deviations are Given in Parentheses

Figure 4. Bond Angles for 56 b . The Standard Deviations are Between 0.11 and $0.16^{\circ}$. Additional Bond Angles are $0(1)-C(5)-C(6)=107.2^{\circ}, C(4)-C(5)-C(6)=113.0^{\circ}, C(8)-C(11)-C(13)=112 .{ }^{\circ}$ and $C(12)-C(11)-C(6)=107.6^{\circ}$
by $H$ atoms. The lactone ring is in a flattened twist $\left(C_{2}\right)$ conformation as can be seen from the values of the internal torsion angles in Table X. The approximate two-fold axis passes through atom $C(2)$ and bisects the $C(4)-C(5)$ bond. The $\alpha, \beta$-unsaturated $\gamma$-1actone in a group of natural products $10,15,54,91,92,94$ show a wide range of conformations for the five-membered ring. Both the envelope $\left(C_{s}\right)$ and twist $\left(C_{2}\right)$ conformations have been observed with varying degrees of flatness. $15,54,92$ The factors affecting the conformation in the present compound may include an attempt to minimize contacts with $0(1)$ and the axial hydrogen atom or atoms $C(7)$ and $C(9)$ and at the same time minimize contacts between the hydrogen atoms on atom $C(4)$ and the axial hydrogen atoms of atoms $C(6)$ and $C(10)$. In addition, crystal packing forces may also affect the conformation. It is interesting to point out that since many compounds possessing an $\alpha, \beta$-unsaturated $\gamma$-lactone show biological activity which is attributed to this functional group that a structure activity relationship might exist which involves the conformation of the lactone ring. At this time, however, sufficient data is not available to test this hypothesis. The t-butyl group which anchors the conformation by occupying the equatorial position on $C(8)$ is staggered with respect to the ring. The values of two representative torsion angles are $C(7)-C(8)-C(11)-C(14)=174.8^{\circ}$ and $C(9)-C(8)-$ $C(11)-C(12)=182.6^{\circ}$. One of the primary reasons for using $X-r a y$ diffraction to determine this structure was to ascertain whether the 0 atom or ${ }^{\prime} \mathrm{CH}_{2}$ group occupies the axial position of the spiro $C$ atom. A11 data including electron densities, bond lengths, least-squares refinement and location of $H$ atoms show conclusively that the 0 atom occupies the axial position with no evidence for a disordered structure.

The bond lengths in the lactone compare well with the values reported for several natural products. $10,15,54,91,92,94$ The weighted averages compiled from the literature are $0(1)-C(2)=1.356, C(2)-C(3)=$ $1.486, C(3)-C(4)=1.506, C(4)-C(5)=1.542, C(5)-0(1)=1.461, C(2)-$ $O\left(2^{\prime}\right)=1.205$ and $C(3)-C\left(3^{\prime}\right)=1.324 \AA$. The largest difference $\circ$ (0.023 A) is for the $C(5)-0(1)$ distance; all other differences are less than 0.01 A . The $\mathrm{C}(8)-\mathrm{C}(11)$ bond length is slightly lengthened which is not unexpected for a bond to a bulky substituent. Inspection of bond angles indicate that the surroundings of atoms $C(2)$ and $C(3)$ are planar having the sum of bond angles equal to 360.0 and $359.9^{\circ}$, respectively. The bond angles in the lactone ring show the same trends as those observed for the natural products.

The molecule could contain a mirror plane passing through atoms $C(5), C(8), C(11)$ and the midpoints between $C(7)-C(9)$ and $C(6)-C(10)$. However, if one calculates a least-squares plane through these points one finds that the entire lactone group is significantly out of the plane. The distances from this plane are as follows: $0(1)-0.019$, $C(2)-0.477, C(3)-0.601, C(4)-0.010, C(5)-0.003, O\left(2^{\prime}\right)-0.711$ and $C\left(3^{\prime}\right)-1.146 \AA$. One could also construct a stereoisomer of the molecule in the present structure by taking the mirror image through the least-squares plane thus flipping the lactone group to the opposite side. This molecule would have exactly the same energy and most likely occurs in both solution and the solid state. Although one conformer is selectively crystallized in the present structure, no attempt was made to determine which conformer precipitates although the question
could be resolved using the anomalous scattering of the oxygen atoms. ${ }^{19}$ It is not possible for both to exist in a disordered crystal structure because the space requirements of a disordered lactone would be too great. Experimentally no evidence for disorder was found as the refinement of thermal parameters for all $\mathrm{C}, \mathrm{O}$ and H atoms of the lactone group was normal and no residual electron density was found in this area of the final difference Fourier map. A calculation of intermolecular distances revealed an unusually short contact between $O\left(2^{\prime}\right)$ and $H\left(3^{\prime} a\right)$ of $2.41 \AA\left[H\left(3^{\prime}\right)\right.$ transformed by ( $x, y, z-1$ )] which is about $0.2 \AA$ shorter than the sum of the van der Waal radii.

To summarize, the thermodynamic parameters reported herein show a slight predominance $\left(\Delta G^{\circ}-88{ }^{\circ} \mathrm{C}=0.10 \mathrm{kcal} / \mathrm{mol}\right)$ for conformer 56a (C-0 bond axial) in the equilibrium $\underset{\sim}{56 a} \stackrel{\rightharpoonup}{\leftarrow} 57$ a in acetone- ${\underset{6}{6}}_{6}$. This was demonstrated conclusively by the determination of the integrated areas

56
 579
at very low temperatures and supported strongly by values (e.g. $\Delta G^{\circ}{ }_{13}{ }^{\circ} \mathrm{C}=0.22 \mathrm{kcal} / \mathrm{mol}$ ) calculated by the chemical shift method at higher temperatures. It was also noted that while it is the $O(1)-$ $C(5)$ bond and the $C(4)-C(5)$ bonds which alternate between the axial and equatorial positions in the equilibrating six-membered ring, the
substituents on the adjacent carbons may also play an important role in directing the equilibrium, especially in regards to their ability to interact with the solvent. This was graphically illustrated in the apparent reversal of the conformational preference of $56 \mathrm{a} \stackrel{\rightharpoonup}{\leftarrow} 57 \mathrm{a}$ in $\operatorname{DCCl}_{3}\left(\Delta \mathrm{G}^{\mathrm{O}}{ }_{37}{ }^{\circ} \mathrm{C}=-0.4 \mathrm{kcal} / \mathrm{mol}\right.$ favoring 57a). A study involving determination of $\Delta G^{\circ}$ at one temperature for a series of substituted spiro dioxolanes ${ }^{89}$ has also indicated that these types of interactions can markedly influence the equilibrium process so that predictions of values for the thermodynamic parameters, based on analogous systems in which substituents in the five-membered ring are different, must be done with care.

Variable temperature studies of the equilibrium constant given herein demonstrate the need for careful evaluation of general experimental techniques for the determination of thermodynamic parameters as applied to specific systems. Whereas both the "corrected" 47 and "uncorrected" ${ }^{16}$ chemical shift methods can give values at specific temperatures which are in close agreement to those obtained by integrated areas, it is necessary to evaluate the temperature dependence of the conformational equilibrium to establish which method is best for a particular system.

Interestingly, the $\Delta G^{*}$ values ( $10.9 \mathrm{kcal} / \mathrm{mol}$ ) determined for 56a $\underset{\sim}{~ 57 a ~ a r e ~ s i m i l a r ~ t o ~ t h o s e ~ r e p o r t e d ~ f o r ~ s e v e r a l ~ 1,1-d i s u b s t i t u t e d ~}$ cyclohexanes (e.g. 1,1-dimethoxycyclohexane, $\left.\Delta G^{*}=10.8 \mathrm{kcal} / \mathrm{mol}\right) .{ }^{26}$ Comparison with the values of $\Delta G{ }^{*}$ determined for cyclohexane ( $10.5 \mathrm{kcal} / \mathrm{mol})^{4}$ suggest that the spiro substitution actually stabilizes the ground state conformers relative to the transition state by a modest amount. Additional substitution on the six-membered ring,
which might increase the energy of the two conformers relative to the transition state via steric 1,3-interactions, might be expected to lower the ring reversal energy barrier. Studies of $1,1,3,3-$ tetra- and $1,1,3,3,5,5$-hexa-substituted cyclohexanes support this conclusion. ${ }^{26}$ Hence it is not surprising that the coalesence phenomenon is not observed for either $56 \mathrm{c} \stackrel{\rightharpoonup}{\leftarrow} 57 \mathrm{c}$ or $56 \mathrm{~d} \underset{\sim}{~ 57 d ~ f o r ~ t e m p e r a t u r e s ~}$ as low as $177^{\circ} \mathrm{K}\left(-96^{\circ} \mathrm{C}\right)$.

The X-ray analysis conclusively identified cis-8-t-butyl-3-methyl-ene-1-oxaspiro[4.5]decan-2-one as structure 56b. Several novel features of this molecule were notable. The significant flattening of the six-membered ring at the spiro end implied that a distinct interaction exists between the axial oxygen and the axial H atoms on $\mathrm{C}(7)$ and C(9). It was also evident from the X-ray analysis that two forms of the twisted lactone ring could exist, and that these forms probably would rapidly interconvert in solution. However, it was concluded that any such interconversion would be much too fast to be detectable on the NMR time scale.

## Suggestions for Future Work

In view of the work presented herein, a more detailed analysis of solvent effects upon the conformational equilibria of $56 \mathrm{a} \vec{\sim} 57 \mathrm{a}$ would be of intrinsic value in perhaps determining the nature of the solventsolute complex. This would necessitate use of PFT-NMR techniques since the solubility characteristics of $56 a \vec{\sim} 57$ are very limited in most organic solvents examined to date. Possible candidates for appropriate solvent systems include the freons, mixtures of methanol
and higher molecular weight branched alcohols, and possibly chloroformmethanol mixes as were used by Uebel and co-workers. ${ }^{89}$ The use of such a solvent group(s) with wide polarity properties should be instructive with respect to shifts in the equilibrium by hydrogen bonding or highly polar solvent-solute interactions.

Selective deuteration of the six-membered ring in cis-8-t-buty1-3-methylene-1-oxaspiro[4.5]decan-2-one (56b) could allow one to determine axial and equatorial coupling constants between the $H(7)$ and

$H(9)$ protons. This could permit the calculation of an $R$ value ${ }^{63}$ for this molecule in solution, and hence permit an assessment of a possible deformation in the cyclohexane ring due to the t-butyl group (or lactone). Comparisons could then be made of the molecular configuration in the crystalline state from the X -ray data and in solution and with model systems.

CHAPTER III

EXPERIMENTAL

Melting points for compounds $56 b, 57 b$ and $56 d$ (or 57d) were obtained on a Thomas-Hoover melting point apparatus. Melting points of 56a (or 57a) and 56 (or 57c) were obtained on a Fisher-Johns melting point apparatus by first cooling the block with ice and then placing the crystal on the block to allow the block to warm slowly. All melting and boiling points were uncorrected. Cyclohexanone (58a) [bp $\left.56-57^{\circ}(20 \mathrm{~mm})\right], 4-t-b u t y l c y c l o h e x a n o n e(58 b)\left(m p ~ 47-49^{\circ} \mathrm{C}\right)$ and $3,3,5,5$-tetramethylcyclohexanone (58d) [bp $92-94^{\circ} \mathrm{C}(20 \mathrm{~mm})$ ] were obtained commercially and purified by vacuum distillation. Tetrahydrofuran was dried by distillation first from $N a H$ and then from LiAlH $_{4}{ }^{-}$ All other solvents were distilled and then dried over Na when appropriate. The IR spectra were recorded on a Beckman IR-5A spectrometer and were calibrated with the $1602 \mathrm{~cm}^{-1}$ band of polystyrene. The mass spectral data, when obtainable, are presented as per cent of and normalized to the most intense ion. All spectral data, with the exception of mass spectral data, are reported in Table II in Results and Discussion. Elemental analyses were performed by Galbraith Laboratories, Knoxville, Tennessee.

NMR and DNMR Spectroscopic Studies

The ${ }^{1}{ }_{H}$ NMR spectra were recorded on a Varian XL-100(15) NMR
spectrometer equipped with a Nicolet TT-100 PFT accessory, operating at 100.1 MHz with $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{Si}$ as an internal reference. All controlled temperature spectra were recorded in acetone- $d_{6}$ in the FT mode with the solvent providing the necessary deuterium lock. A pulse width (P2) of $5.7 \mu \mathrm{sec}$ was used with a $4-6 \mathrm{sec}$ delay (D5) between pulses. Temperature control was provided by a Varian temperature controller. A capillary of $\mathrm{CH}_{3} \mathrm{OH}$ with a trace of HCl present was placed in a 5 mm NMR tube containing 0.5 mL acetone- $\underline{d}_{6}$ and was used to calibrate the temperature according to the method of Van Geet. ${ }^{9}$ Calibrations were done before and after each spectrum, and those spectra whose temperature calibrations differed by more than $1^{\circ} \mathrm{C}$ were discarded and the shifts were reexamined at that temperature. Integrations were done electronically on the computer of the TT-100 and cross-checked using hand planimetry on the plotted spectra.

The ${ }^{13} \mathrm{C}$ NMR spectra were recorded with the unit operating at 25.2 MHz in the FT mode with the solvent providing the deuterium lock. A pulse width of $15.5 \mu$ was used with a 12 sec delay between pulses with $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{Si}$ as an internal standard.

Preparation of Ethy1 $\alpha$-Bromomethylacrylate (24)

Ester 24 was synthesized from 288 g ( 1.8 mol ) of diethyl malonate, bp $98^{\circ} \mathrm{C}$ (18 mm), using the method of Ramarajan and co-workers. 81 This multi-step procedure gave 82.3 g ( $0.426 \mathrm{~mol} 23 \%$ ) of ester 24 . $\mathrm{bp} 56^{\circ} \mathrm{C}(2.0 \mathrm{~mm})\left[1\right.$ it. $\left.{ }^{21} \mathrm{bp} 44-45^{\circ} \mathrm{C}(1.7 \mathrm{~mm})\right]$.

Preparation of 3,3 -Dimethy1cyclohexanone ( $\underbrace{58 c})^{24}$

In a 1000 mL , round-bottom flask, equipped with a condenser and a
continuous water extractor (Dean-Stark trap) were placed 50 g ( 0.357 mol ) of 5,5-dimethyl-1,3-cyclohexadione ( $\underset{\sim}{\sim}$ ) $\left(\mathrm{mp} 147-150^{\circ} \mathrm{C}, 51 \mathrm{~g}(65 \mathrm{~mL}\right.$, 1.12 mol ) of absolute ethanol (distilled from CaO and then from Mg ) and 2 g ( 0.012 mole) of $\mathrm{p}-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{SO}_{3} \mathrm{H}$ (mp $104-106^{\circ} \mathrm{C}$ ) in 300 mL of benzene (dried over Na ). The reaction mixture was allowed to reflux until water ceased to be collected in the trap. The mixture was then stripped of solvent on a roto-evaporator, and then fractionally distilled under reduced pressure to give 50.3 g ( $0.299 \mathrm{~mol}-84 \%$ ) of 5,5-dimethyl-3-ethoxy-2-cyclohexenone (62) ; bp $125^{\circ} \mathrm{C}$ ( 3.0 mm ) [1it. ${ }^{24}$ bp $93^{\circ} \mathrm{C}$ ( 1 mm )].

To solution of 50 g ( 0.297 mol ) of 5,5-dimethyl-3-ethoxy-2-cyclohexenone (62) in 280 mL of ether (dried over Na ) in a 500 mL , 3-necked, round-bottom flask equipped with stirrer, condenser, and $\mathrm{N}_{2}$ inlet and packed in ice was added with care $2.8 \mathrm{~g}(0.073 \mathrm{~mol})$ of $\mathrm{LiAlH}_{4}$. The mixture came to a gentle boil upon each addition of LiAlH $_{4}$ and was allowed to cool between additions. The ice was removed and the reaction mixture was stirred for 1 h at room temperature. The solution was then poured with extreme caution into 550 mL of ice-cold $\mathrm{H}_{2} \mathrm{O}$ and a gas $\left(\mathrm{H}_{2}\right)$ evolved. The solution was made acidic with dilute ( 6 M ) $\mathrm{H}_{2} \mathrm{SO}_{4}$ and the ether layer was separated from the aqueous layer. The aqueous layer was then washed with an additional 100 mL of ether; the ether portions were combined and dried $\left(\mathrm{MgSO}_{4}\right)$. Roto-evaporation of the solvent, followed by fractional distillation under reduced pressure afforded 12.5 g ( 0.101 mol - $34 \%$ ) of 5,5-dimethyl-2-cyclohexenone ( 63 ) ; bp $82-85^{\circ} \mathrm{C}(25 \mathrm{~mm})\left[1 \mathrm{it}{ }^{24} \mathrm{bp} 75^{\circ} \mathrm{C}(15 \mathrm{~mm})\right]$. This ketone 63 ( $31.7 \mathrm{~g}, 0.255 \mathrm{~mol}$ ) was reduced over a 12 -h period by the action of
$\mathrm{H}_{2}$ (1 atm) over $\mathrm{Pd}-\mathrm{C}$ (10\%) in a Parr unit with $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{C}_{2} \mathrm{H}_{5}$ as the solvent. Distillation afforded $18.9 \mathrm{~g}(0.150 \mathrm{~mol}-60 \%)$ of 3,3 -dimethylcyclohexanone (58c); bp $49^{\circ} \mathrm{C}(3.2 \mathrm{~mm})\left[1 \mathrm{it}{ }^{13}\right.$ bp $\left.174-175^{\circ} \mathrm{C}(757 \mathrm{~mm})\right]$.

## Preparation of 2,2 -Dimethylcyclohexanone (58e) ${ }^{3}$

To an ice-cold solution of $27 \mathrm{~g}(0.50 \mathrm{~mol})$ of $\mathrm{NaOCH}_{3}, 37 \mathrm{~g}(0.50$ mol) of ethyl formate in 190 mL of benzene (dried over Na ) in a 100 mL , 3-necked, round-bottom flask equipped with a mechanical stirrer, condenser, $\mathrm{N}_{2}$ gas inlet and addition funnel was added 24.5 g ( 0.25 mol ) of cyclohexanone (58a) in 100 mL of benzene. An additional 100 mL of benzene was added, and the mixture was stirred overnight. After addition of 200 mL of ice-cold $\mathrm{H}_{2} \mathrm{O}$, the layers were separated, and the organic layer was washed with 100 mL of $5 \% \mathrm{NaOH}$. The combined aqueous layers were acidified with dilute ( 6 M ) HCl , saturated with NaCl and extracted ( 200 mL of ether). The ether layers were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and then concentrated. Distillation afforded 19.1 g ( 0.151 mol-60.5\%) of 2 -(hydroxymethylene)cyclohexanone (64); bp $70^{\circ} \mathrm{C}(5 \mathrm{~mm})$ $\left[1 \mathrm{it}{ }^{3} \mathrm{bp} 70-72{ }^{\circ} \mathrm{C}(5 \mathrm{~mm})\right]$.

Ketone $\underset{\sim}{64}(19 \mathrm{~g}, 0.151 \mathrm{~mol})$ was allowed to react with 15 g ( 0.174 mol ) of n -butylmercaptan (undistilled) and 0.03 g ( 0.00015 mol ) of $\mathrm{p}^{-} \mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{SO}_{3} \mathrm{H}$ in 115 mL of benzene in a 250 mL , round-bottom flask equipped with a continuous water extractor (Dean-Stark), condenser and $\mathrm{N}_{2}$ inlet. After 2.75 mL of $\mathrm{H}_{2} \mathrm{O}$ had been collected ( 8 h ), the reaction was cooled and then washed with $10 \% \mathrm{NaHCO}_{3}$. Drying ( $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ) of the organic layer overnight, followed by distillation, afforded 17 g ( $0.086 \mathrm{~mol}-56 \%$ ) of $2-\mathrm{n}$-butylthiomethylene cyclohexanone (65); bp $85-88^{\circ} \mathrm{C}(0.05 \mathrm{~mm})\left[1 \mathrm{it} .{ }^{7} \mathrm{bp} 120-130^{\circ} \mathrm{C}(0.5 \mathrm{~mm})\right]$.

An ether solution ( 180 mL ) of ketone, $\underset{\sim}{65}$, ( $7 \mathrm{~g}, 0.035 \mathrm{~mL}$ ) and $1.25 \mathrm{~mL}(0.07 \mathrm{~mole})$ of $\mathrm{H}_{2} \mathrm{O}$ was added over a 30 -min period to 1.47 g ( 0.21 g at) of Li in 700 mL of liquid $\mathrm{NH}_{3}$ in a $2-\ell$, 3-necked, roundbottom flask equipped with stirrer (polypropylene bar), a 500 mL addition funnel and a dry ice-acetone condenser. After an additional $30 \mathrm{~min}, 360 \mathrm{~mL}$ of dry ether was added followed by a solution of $\mathrm{CH}_{3} \mathrm{I}$ ( $60.2 \mathrm{~g}, 0.42 \mathrm{~mol}$ ) in 180 mL of ether. The reaction was stirred for 30 min, and then the $\mathrm{NH}_{3}$ was allowed to evaporate slowly. The resulting oily residue was extracted with either and the resulting extract was dried $\left(\mathrm{MgSO}_{4}\right)$ and vacuum distilled to yield 1.9 g ( $0.015 \mathrm{~mol}-43 \%$ ) of 2,2-dimethylcyclohexanone (58e); bp $47^{\circ} \mathrm{C}$ ( 4 mm ) [1it. ${ }^{45} \mathrm{bp} 170-172^{\circ} \mathrm{C}$ (750 mm ) ].

> General Procedure for Synthesis of the
> $\alpha$-Methylene Spiro Lactones (56a-56e, 57a-57e) from the Ketones 58a-58e

A solution of $5.3 \mathrm{~g}(0.0275 \mathrm{~mol})$ of ester $\underset{\sim}{24}$ in 15 mL of dry THF was added slowly with stirring to a suspension of $1.7 \mathrm{~g}(0.027 \mathrm{~g}$ at) of Zn (20 mesh) dispersed in a solution of 0.025 mol of the appropriate ketone $58 \mathrm{a}-58 \mathrm{e}$ in 8 mL of dry THF in a 100 mL , 3-necked, round-bottom flask equipped with magnetic stirrer, condenser, thermometer and $\mathrm{N}_{2}$ inlet. The temperature was allowed to rise during the addition to $45^{\circ} \mathrm{C}$ and was maintained at $50^{\circ} \mathrm{C}$ by gentle heating for two additional hours. After cooling to room temperature, the reaction mixture was poured directly into 200 mL of ice-cold, $5 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ with vigorous stirring. Stirring of the mixture at a reduced speed was continued for 0.5 hr
after the addition, the product separating during this time either as an oil or as a crystalline solid. This product was taken up with ether and the extract was washed with $\mathrm{NaHCO}_{3}$ followed by $\mathrm{H}_{2} \mathrm{O}$ and was dried ( $\mathrm{MgSO}_{4}$ ) overnight.

> Synthesis and Purification of 3-Methylene-1oxaspiro[4.5]decan-2-one (56a or 57a)

Cyclohexanone ( $3.6 \mathrm{~g}, 0.037 \mathrm{~mol}$ ) was allowed to react in 35 mL of dry THF with $\mathrm{Zn}(2.63 \mathrm{~g}, 0.40 \mathrm{~g}-\mathrm{at})$ and ester $24(7.95 \mathrm{~g}, 0.041 \mathrm{~mol})$ as described above. The crude produce $5 \underset{\sim}{~} \stackrel{\rightharpoonup}{\sim} 57$ a was isolated as an oil from the ether by roto-evaporation and was taken up in a minimum ( 50 mL ) of hot commercial hexanes and the resulting solution was filtered. The solution was chilled slowly to $-78^{\circ} \mathrm{C}$. A crystalline product formed and was filtered off at $-78^{\circ} \mathrm{C}$ using a jacketed funnel. Vacuum drying of the crystals at room temperature $\left(20^{\circ} \mathrm{C}\right)$ gave 5.2 g ( $86 \%$ ) of 56 (or 57 a ) ; mp $26-27.5^{\circ} \mathrm{C}$; bp $76-77^{\circ} \mathrm{C} /\left(0.05 \mathrm{~mm}\right.$ ) [1it. ${ }^{7} \mathrm{bp}$ $\left.80-85^{\circ} \mathrm{C} /(1.0 \mathrm{~mm})\right]$.

Anal. Calcd. for $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}_{2}: \mathrm{C}, 72.26 ; \mathrm{H}, 8.49$.
Found: $\mathrm{C}, 72.05 ; \mathrm{H}, 8.29$.

Synthesis and Purification of cis- and trans-8-t-Buty1-3-methylene-1-oxaspiro[4.5]decan-2-one ( $\underset{\sim}{\sim}$ and 57 b )

The reaction of 4-t-butylcyclohexanone ( 58 b $)(3.86 \mathrm{~g}, 0.025 \mathrm{~mol})$ with ester $\underset{\sim}{24}(5.3 \mathrm{~g}, 0.2075 \mathrm{~mol})$ and $\mathrm{Zn}(1.76 \mathrm{~g}, 0.027 \mathrm{~g}-\mathrm{at})$ in 23 mL of THF as described above afforded 3.6 g ( $65 \%$ ) of a mixture of

56 b and $57 \mathrm{~b}, \mathrm{mp} 63-71^{\circ} \mathrm{C}$. NMR analysis (in $\mathrm{CCl}_{4}$ ) of this crude product revealed a ratio of $4: 1$ for $56 \mathrm{~b}: 57 \mathrm{~b}$. Careful fractional crystallization ( $\mathrm{CH}_{3} \mathrm{OH}$ ) initially afforded colorless crystals of 56 b , $\mathrm{mp} 83-84^{\circ} \mathrm{C}$, in which the trans-isomer 57 b was no longer detectable via NMR analysis. Subsequent fractions showed evidence of both isomers. These latter fractions of isomers were chromatographed on a column of Florisil (Research Specialties Co.) in a ratio of 30:1 adsorbant:substrate, using 150 mL of hexane, followed by 100 mL of $50: 50$ benzene:hexane and then 100 mL of benzene. Those fractions containing the trans-isomer 57 b identified via NMR analysis were combined and rechromatographed as described above. The trans-isomer 57 b ( 50 mg ) was isolated from the benzene fractions, $\mathrm{mp} 84-85^{\circ} \mathrm{C}$. The total yield of product was 3.6 g ( $65 \%$ ) and was composed of 2.65 g ( $48 \%$ ) of cis-isomer 56 b and 50 mg ( $1.0 \%$ ) of trans- 57 b along with 0.91 g ( $16.4 \%$ ) of a mixture of the two. Analysis of the two separate isomers gave the following results:

Synthesis and Attempted Purification of
    6,6-Dimethy1-3-methylene-1-
    oxaspiro[4.5]decan-2-one
        (56e or 57e)
```

The reaction of 2,2-dimethylcyclohexanone (58e) (1.9 g, 0.015 mol$)$
with ester $24(2.12 \mathrm{~g}, 0.011 \mathrm{~mol})$ and $\mathrm{Zn}(0.72 \mathrm{~g}, 0.011 \mathrm{~g}-\mathrm{at})$ in 15 mL THF was performed as described above. The product was isolated from the either extract as an oil. Attempts to crystallize the cryde product either from a solution of hexanes or neat gave a glassy, amorphous solid. Distillation of this product was accomplished under reduced pressure $\left[b p 57-59^{\circ} \mathrm{C}(0.05 \mathrm{~mm})\right.$ ] in a spinning band micro distillation apparatus, 1.16 g ( $40 \%$ ). The NMR of the resulting distillate showed the presence of several trace contaminates (Plate XII). Surprisingly, the product polymerized rapidly in the dark even under refrigeration.

Elemental analysis confirmed the presence of contaminants, but the $1_{H}$ NMR spectrum (Plate XIII) had the correct signals for the expected compound at $\delta 0.90$ (s) 3 H ; 0.96 (s) $3 \mathrm{H} ; 1.1-1.9$ (m) $8 \mathrm{H} ; 2.44$, 2.62, 3.02 , 3.20 ( q of t ) 2 H ; 5.64 (d of t) 1 H ; 6.06 (d of t) 1 H.

Anal. Calcd. for $\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{O}_{2}$ : C, 74.19; H, 9.34.
Found: C, 73.30; H, 8.98.

## X-Ray Analysis and Structure Refinement

Crystals suitable for X-ray intensity measurement were obtained by cooling a solution prepared by dissolving a small amount of 56 b in hot methanol. Initial diffraction experiments showed the crystals to be orthorhombic. The crystal data are: $\mathrm{C}_{14} \mathrm{H}_{22} \mathrm{O}_{2}, \mathrm{M}=222.32$, space group ${ }^{2}{ }_{1} 1_{1}{ }_{1}{ }^{2} 1$, $a=11.455(2), b-18.356(2), c=6.100(1) \mathrm{A}$, $\mathrm{V}=1282.6{ }^{\circ} \mathrm{A}^{3}\left(\right.$ at $\left.-135^{\circ} \mathrm{C}\right) \mathrm{Z}=4, \mathrm{~F}(000)=488$, Ni filtered CuK $\alpha$ radiation: $\lambda(\mathrm{CuK} \alpha)=1.54051 \AA$ for determination of cell constants and $\lambda\left(\operatorname{CuK} \overline{\alpha_{1}}\right)=1.54178 \AA$ for intensity data. The unit cell parameters were
determined by least-squares to the $+2 \theta$ and $-2 \theta$ values of 44 reflections distributed throughout all regions of reciprocal space.

A total of 1551 intensities representing all unique reflections with $2 \theta \leq 150$ were measured using a Nonius CAD-4 automatic diffractometer and $-2 \theta$ scan techniques. The scan with $(\Delta \theta)$ was adjusted for dispersion and calculated as $\Delta \theta=(1.0+0.1 \text { tan } \theta)^{0}$ for each refelction. A receiving aperture with variable width calculated as $(4.0+$ $0.86 \tan \theta) \mathrm{mm}$ and constant height of 6.00 mm was located 173 mm from the sample. A maximum of 60 s was spent on each intensity with $2 / 3$ of the time spent scanning the peak and $1 / 6$ of the time spent scanning each the left and right background. Less than 60 s was used if 40,000 counts could be obtained with a faster scan speed. The total time was divided into two scans and if the results of those two scans varied by more than $3 \sigma$ up to three additional scans were made. $A$ monitor reflection was measured after every 25 observations and did not show a systematic variation during data collection. Three additional reflections were re-centered after every 100 measurements and a new orientation matrix was automatically calculated if any angle changed by more than $0.1^{0}$ from its original value. A total of 122 intensities could not be distinguished from the background on the basis that the intensity (I) was less than $2 \sigma$ (I). These reflections were assigned an intensity of 0.95 times the square root of the total count for the purpose of further data analysis. The value of 0.95 was chosen such that the sum of the observed magnitudes of the structure factor was equal to the sum of the calculated magnitudes for this class of data.

The observed intensities were corrected for Lorentz and polarization effects and structure factor magnitudes derived. Absorption
corrections were not applied as the calculated linear absorption coefficient had a value of only $6.44 \mathrm{~cm}^{-1}$. Throughout the data analysis an experimental weight, based on counting statistics, was assigned to each structure factor. ${ }^{93}$

The structure was solved using direct methods and the computer program MULTAN. ${ }^{30}$ An E-map based on the magnitudes of the 160 largest normalized structure factors, $|E|$ 's, and the MULTAN phase set having the largest absolute figure of merit and lowest residual revealed the positions of the 16 non-hydrogen atoms. An initial structure factors calculation gave an $R$ value ( $\Sigma\left|\left|\mathrm{kF}_{\mathrm{o}}\right|-\left|\mathrm{F}_{\mathrm{c}}\right|\right| / \Sigma\left|\mathrm{kF}_{\mathrm{o}}\right|$ ) equal to $24.2 \%$ where $\left|F_{o}\right|$ is the observed structure factor magnitude, $F_{c}$ is the calculated structure factor and $k$ is a scale factor which places the observed data on an absolute scale. After the block-diagonal leastsquare refinement of the isotropic model had converged ( $R=10.3 \%$ ) a difference Fourier map was claculated from which the position of all hydrogen atoms were located. After several more cycles of refinement all non-hydrogen atoms were given anisotropic thermal parameters. The refinement using anisotropic thermal parameters for $C$ and $O$ atoms and isotropic thermal parameters for $H$ atoms was terminated when all shifts were sam11 fractions of the corresponding estimated standard deviation. The R value based on the final parameters (Table XIII and XIV) was $3.8 \%$. The standard error in an observation of unit weight, $\left[\Sigma \omega \Delta F^{2} /(m-n)\right]^{1 / 2}$, is 1.18 e , where $\omega$ is the experimental weight, $\Delta \mathrm{F}$, is the difference between the observed and calculated structure factor magnitudes, $m$ is the number of observations and $n$ is the number of parameters in the refinement.

## TABLE XIII

POSITIONAL PARAMETERS ( $\mathrm{x} \times 10^{5} ; \mathrm{y} \times 10^{5} ; \mathrm{z} \times 10^{4}$ ) AND ANISOTROPIC THERMAL PARAMETERS ( $\mathrm{x} 10^{4}$ ) FOR C AND 0 ATOMS. A11 structure refinement was carried out using the block-diagonal least-squares program of $A^{\prime} h^{2}$ in which the quantity $\Sigma\left(\mathrm{wF}_{\mathrm{o}}-\mathrm{F}_{\mathrm{c}}\right)^{2}$ was minimized. All Fourier maps were calculated using Ahmed's Fourier transform program. ${ }^{1}$ Scattering factors for $C$ and 0 atoms were taken from the International Tables for X-ray Crystallography, Vol. III 44 while those for $H$ atoms were taken from Stewart, Davidson and Simpson. 86 A final difference Fourier map contained no peaks greater than 0.16 e $\mathrm{A}^{-3}$. A final structure factor analysis showed that $\sum \mathrm{w} \Delta \mathrm{F}^{2}$ did not vary with either $\sin \theta / \lambda$ or $\left|F_{o}\right|$ thus validating the weighting scheme used. The positional parameters and anisotropic thermal parameters for nonhydrogen atoms are given in Table XIII. The positional parameters and isotropic thermal parameters for $H$ atoms are given in Table XIV.

Mathematical Manipulations Used in Error<br>Analysis - Derivations of Equations

(2) and (3)

The approximate relative error in $\Delta G^{\circ}$ resulting from errors in
$K_{e q}$ and $T$ is given by the general expression:

$$
\begin{align*}
& \left(\sigma_{\Delta G^{o}}\right) /\left(\Delta G^{o}\right) \simeq\left\{\left[\partial\left(\Delta G^{o}\right) / \partial\left(K_{e q}\right)\right]^{2}\left(\sigma_{K_{e q}} / \Delta G^{o}\right)^{2}\right.  \tag{10}\\
& \left.\quad+\left[\partial\left(\Delta G^{\mathrm{o}}\right) / \partial \mathrm{T}\right]^{2}\left(\sigma_{\mathrm{T}} / \Delta \mathrm{G}^{\mathrm{o}}\right)^{2}\right\}^{\frac{1}{2}}
\end{align*}
$$

From Eq. (1) (page 25) the appropriate partial derivatives are:

$$
\begin{aligned}
\partial\left(\Delta G^{0}\right) / \partial\left(K_{e q}\right) & =-R T / K_{e q} \\
\partial\left(\Delta G^{\circ}\right) / \partial T & =-R \ln K_{e q}
\end{aligned}
$$

Substituting these expressions into Eq. (10) above, one obtains:

$$
\begin{aligned}
\left(\sigma_{\Delta G^{o}}\right) /\left(\Delta G^{o}\right) & \simeq\left\{\left(-R T / K_{e q}\right)^{2}\left[\sigma_{K_{e q}} /\left(-R T \ln K_{e q}\right)\right]^{2}\right. \\
& \left.+\left(-R \ln K_{e q}\right)^{2}\left[\sigma_{T} /\left(-R T \ln K_{e q}\right)\right]^{2}\right\}^{\frac{1}{2}}
\end{aligned}
$$

Combining like terms, one obtains Eq. (2), i.e.:

$$
\left(\sigma_{\Delta G^{o}} / \Delta G^{o}\right) \simeq\left\{\left(\sigma_{T} / T\right)^{2}+\left(\ln K_{e q}\right)^{-2}\left(\sigma_{K_{e q}} / K_{e q}\right)^{2}\right\}^{\frac{1}{2}}
$$

The expression below was used to calculate $\Delta \mathrm{H}^{\mathrm{O}}$.

$$
\Delta \mathrm{H}^{\mathrm{o}}=-\mathrm{R} \mathrm{~d}\left(\ln \mathrm{~K}_{\mathrm{eq}}\right) / \mathrm{d}(1 / \mathrm{T})
$$

For two specific measurements of $K_{e q}, K_{1}$ and $K_{2}$, at temperatures $\mathrm{T}_{1}$ and $\mathrm{T}_{2}$, respectively, the above expression becomes:

$$
\begin{equation*}
\Delta H^{o}=-R\left(\ln K_{2}-\ln K_{1}\right) /\left(1 / T_{2}-1 / T_{1}\right) \tag{11}
\end{equation*}
$$

The approximate relative error in $\Delta H^{\circ}$ resulting from errors in $K_{1}$, $\mathrm{K}_{2}, \mathrm{~T}_{1}$ and $\mathrm{T}_{2}$ is given by the general expression:

$$
\begin{align*}
& \left(\sigma_{\Delta \mathrm{H}^{\mathrm{O}}}\right) /\left(\Delta \mathrm{H}^{\mathrm{O}}\right) \simeq\left\{\left[\partial\left(\Delta \mathrm{H}^{\mathrm{o}}\right) / \partial \mathrm{K}_{2}\right]^{2}\left(\sigma_{\mathrm{K}_{2}} / \Delta \mathrm{H}^{\mathrm{o}}\right)^{2}+\left[\partial\left(\Delta \mathrm{H}^{\mathrm{o}}\right) / \partial \mathrm{K}_{1}\right]^{2}\left(\sigma_{\mathrm{K}_{1}} / \Delta \mathrm{H}^{\mathrm{o}}\right)^{2}\right. \\
& \left.+\left[\partial\left(\Delta \mathrm{H}^{\mathrm{o}}\right) / \partial \mathrm{T}_{2}\right]^{2}\left(\sigma_{\mathrm{T}_{2}} / \Delta \mathrm{H}^{\mathrm{o}}\right)^{2}+\left[\partial\left(\Delta \mathrm{H}^{\mathrm{o}}\right) / \partial \mathrm{T}_{1}\right]^{2}\left(\sigma_{\mathrm{T}_{1}} / \Delta \mathrm{H}^{\mathrm{o}}\right)^{2}\right\}^{\frac{1}{2}} \quad \text { Eq. } \tag{12}
\end{align*}
$$

where $\sigma_{K_{2}}, \sigma_{K_{1}}, \sigma_{T_{2}}$ and $\sigma_{T_{1}}$ are the errors associated with $K_{2}$, $K_{1}, T_{2}$ and $T_{1}$, respectively. The appropriate partial derivatives are:

$$
\begin{aligned}
& \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{K}_{2}=-\mathrm{R} /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right) \quad\left(1 / \mathrm{K}_{2}\right) \\
& \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{K}_{1}=\mathrm{R} /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right) \quad\left(1 / \mathrm{K}_{1}\right)
\end{aligned}
$$

$$
\begin{aligned}
& \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{T}_{2}=-\mathrm{R}\left(\ln \mathrm{~K}_{2}-\ln \mathrm{K}_{1}\right)\left[1 /\left(\mathrm{T} / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right)^{2}\left(1 / \mathrm{T}_{2}\right)^{2}\right] \\
& \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{T}_{1}=\mathrm{R}\left(\ln \mathrm{~K}_{2}-\ln \mathrm{K}_{1}\right)\left[1 /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right)^{2}\left(1 / \mathrm{T}_{1}\right)^{2}\right]
\end{aligned}
$$

If the range of temperatures is small, so that $T_{1} \simeq T_{2}$ and $K_{1} \simeq K_{2}$, then:

$$
\partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{K}_{2} \simeq \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{K}_{1} \simeq\left[\mathrm{R} /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right)\right](1 / \mathrm{K}) .
$$

Moreover, one can write the following expression:

$$
\begin{gathered}
\partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{T} \simeq \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{T}_{1} \\
\simeq \mathrm{R}\left(\ln \mathrm{~K}_{2}-\ln \mathrm{K}_{1}\right) /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right)\left[1 /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right)(1 / \mathrm{T})^{2}\right]
\end{gathered}
$$

In this case, $K$ is the value of $K_{e q}$ at the center of the temperature range $T$. Dividing each of these new expressions by $\Delta H^{O}$ [i.e. $-R\left(\ln K_{2}-\ln K_{1}\right) /\left(1 / T_{2}-1 / T_{1}\right]$, one obtains the two equations below:

$$
\begin{aligned}
& \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{K}\left(\Delta \mathrm{H}^{\mathrm{O}}\right)=\left[1 /\left(\ln \mathrm{K}_{2}-\ln \mathrm{K}_{1}\right)\right](1 / \mathrm{K}) \\
& \partial\left(\Delta \mathrm{H}^{\mathrm{O}}\right) / \partial \mathrm{T}\left(\Delta \mathrm{H}^{\mathrm{O}}\right)=\left[1 /\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right)\right](1 / \mathrm{T})^{2}
\end{aligned}
$$

However, the following expression also is valid:

$$
\left(1 / \mathrm{T}_{2}-1 / \mathrm{T}_{1}\right) \simeq \Delta \mathrm{T} / \mathrm{T}^{2}
$$

where $\Delta T=T_{2}-T_{1}$. Substituting these expressions into Eq. (12), and defining $\Delta(\ln K)=\ln K_{2}-\ln K_{1}$ one obtains Eq. (3) (page 27);

$$
\begin{equation*}
\sigma_{\Delta H^{\mathrm{o}}} / \Delta \mathrm{H}^{\mathrm{o}} \simeq\left\{2 \Delta(\ln \mathrm{~K})^{-2}\left(\sigma_{\mathrm{K}} / \mathrm{K}\right)^{2}+2(\mathrm{~T} / \Delta \mathrm{T})^{2}\left(\sigma_{\mathrm{T}} / \mathrm{T}\right)^{2}\right\}^{\frac{1}{2}} \tag{3}
\end{equation*}
$$

One can see a similarity between Eq. (3) and the equation given by Binsch $^{8}$ (see below) for the approximate error associated with $E_{a}$, Eq. (7):

$$
\sigma_{\mathrm{E}} / \mathrm{E}_{\mathrm{a}} \simeq\left\{\left[2 \mathrm{~T}^{2} /(\Delta \mathrm{T})^{2}\right]\left(\sigma_{\mathrm{T}} / \mathrm{T}\right)^{2}+2[\Delta(\ln \mathrm{k})]^{-2}(\sigma \mathrm{k} / \mathrm{k})^{2}\right\}^{\frac{1}{2}}
$$

This is not surprising since the mathematical expressions for $\Delta \mathrm{H}^{\circ}$ and $E_{a}$ are of the same form.

A graphical representation of the error associated with the calculation of $\Delta H^{\circ}$ and $\Delta H^{*}$ by a least-squares analysis of the appropriate plots can be seen in the scatter of points along the leastsquares line in Figures 5, 6, 7 and 8.

Figure 5. Plot of $\ln \mathrm{K}_{\mathrm{eq}}$ vs $1 / \mathrm{T}$ for $56 \mathrm{a} \overrightarrow{ } \rightarrow 57 \mathrm{a}$, Integrated Area Method: $0.024 \mathrm{M} \mathrm{( } \mathrm{\Delta)}$; $0.036 \mathrm{M}(\mathrm{O})$. ## VITA

Danie1 John 0'Donne11
Candidate for the Degree of
Doctor of Philosophy

## Thesis: DNMR STUDY OF THE THERMODYNAMIC AND KINETIC PARAMETERS ASSOCIATED WITH THE RING REVERSAL OF A SPIRO SYSTEM CONTAINING AN $\alpha$-METHYLENE- $\gamma$-BUTYROLACTONE RING

## Major Field: Chemistry

Biographical:
Personal Data: Born in Ames, Iowa, on July 17, 1949; parents, Augustine D. and Jacqueline H. O'Donnell, reside in Slater, Iowa; married to Joyce E. McReynolds on August 28, 1970 and is the father of a son, Sean Daniel, born November 26, 1971.

Education: Graduated from Ballard Community High School, Huxley, Iowa, in 1967; received the Bachelor of Arts degree in Chemistry from Central University of Iowa, Pella, Iowa, in 1971; completed requirements for the Doctor of Philosophy degree in Chemistry at Oklahoma State University, Stillwater, Oklahoma in July, 1978.

Professional Experience: Member of the armed services on active duty from June, 1971 - June, 1974, and was honorably discharged from the Army; teaching assistant from September, 1974 - December, 1977, in the Department of Chemistry at Oklahoma State University; received Phillips Petroleum Company Fellowships for the summers of 1976 and 1977 and was a research assistant during the periods in 1975 (JuneJuly), 1976 (January-May, September-December), 1977 (JanuaryMay) and 1978 (January-June).

Membership in Honorary and Professional Societies: Member of Phi Lambda Upsilon, Sigma Xi, the American Chemical Society and the American Association for the Advancement of Science.

[^0]:    ${ }^{a}$ Isolated yields from a mixture of 56 b and 57 b . Total yield was $65 \%$.
    bompound $56 e \vec{\leftarrow} 57 \mathrm{e}$ failed to crystallize, and partial polymerization occurred in the distillation step.

[^1]:    ${ }^{\mathrm{a}}$ Average chemical shifts (and standard deviations in Hz from internal TMS for a minimum of 4 trials.

[^2]:    ${ }^{\mathrm{b}}$ Chemical Shifts in ppm from TMS.
    Coupling constants in Hz .
    Time averaged value for equilibrating systems, center of triplet.
    Assignment uncertain.
    e Center of doublet of doublets.
    $\mathrm{f}_{\text {Center }}$ of quartet of triplets.
    $\mathrm{g}_{\mathrm{c}}=$ cis; $\underline{t}=$ trans.
