# A STUDY OF HISTORICAL RATES OF RETURN FROM LOW-PRICED COMMON STOCK PORTFOLIOS: <br> 1965-1970 

Report Approved:

## ACKNOWLEDGEMENTS

I would like to take this opportunity to express my sincere appreciation to my adviser, Dr. George Pinches, for his invaluable assistance, encouragement, and interest throughout all phases of this report. Dr. Pinches' insight and comments contributed significantly to the quality of the report. Gratitude is also expressed for the opportunity to share in the presentation of the results of the study before the Southwestern Finance Association in March, 1970.

In addition, for their assistance and interest, I would also like to thank Kermit Hollingsworth, Jill Holmes, Iris McPherson, and Larry Mills.

And finally, I would like to express my sincerest gratitude to my wife, Marilyn, who has worked and sacrificed to give me so much in opportunity, encouragement, and understanding. To her I extend a simple thank you.

## CHAPTER I

## INTRODUCTION

General Introduction and Review

The area of investment returns--always of extreme interest to both instituitional and individual investors-has over the years experienced considerable investigation. Research pertaining to historical evaluation and comparison of returns from alternative investments has been of particular interest in recent years, especially in the analysis of common-stock investments. The initial base for such progress was provided by Fisher and Lorie's exhaustive study of historic rates of return from common stock listed on the New York Stock Exchange during the period $1926-1960^{1}$ (the results have since been updated to $1965^{2}$ ). This study attempted to answer the question of how much profit or loss an individual investor might have realized if he had purchased all New York Stock Exchange common stocks-at five different dates and held them for varying lengths of time during the 35 years from 1926 through 1960. Returns were determined for a variety of assumptions pertaining to individual tax status, dividend reinvestment, and transaction costs. Their findings for the total 35-year period, assuming reinvestment of dividends and annual compounding of rate of return, include: a rate of return of 9 percent for tax-exempt institutions; 8.2 percent for persons in the $\$ 10,000$ income class; and 6.8 percent for persons in the $\$ 50,000$ income class. The authors note "these rates are substantially
higher than for alternative investment media for which data are available." ${ }^{3}$

The significance of these findings stimulated additional investigations of common stock returns. One study, by Brigham and Pappas, ${ }^{4}$ attempted to segregate the rates of return into two components-those returns attributable to dividends and those attributable to capital gains. In total they examined data for 658 industrial and utility firms over the postwar period 1946-1965. As in Fisher and Lorie's study, they focused on aggregate returns and made no distinctions between the price classes of the securities or returns available from selected portfolios. The returns for those years which overlapped Fisher and Lorie's data were quite similiar. Their segmentation of these returns demonstrated that although different percentages of the total return came from the above two components in various years, over the entire period dividends accounted for about 38 percent of the total before-tax return versus 62 percent for capital gains.

To date little has been done in the areas of either aggregative returns, or selected portfolio returns, from common stock within specific price groups. It would seem of particular interest to examine returns from low-priced common stocks due to their risk characteristics, their affordability by non-wealthy investors, their susceptibility to speculative trading, as well as their convenience as a departure point for future price-class studies. Of existing studies two indirect discussions of price-group behavior are noteworthy. Volatility as a function of price has been examined by Clendenin. ${ }^{5}$ He analyzed various time periods and samples of stocks in differing price classes in an attempt to determine the influence of quality and price on price volatility. His
conclusions were:
The truth of the matter is that the percentage price fluctuations in most low-priced stocks are about the same as those in high-priced stocks of the same quality. 6 (emphasis in original)

Three aspects of the study are particularly relevant. First, his classification scheme for 'quality' resulted in the exclusion of all non-dividend yielding securities. This may well have resulted in the elimination of low-priced stocks which achieved large capital gains over the periods. Brigham and Pappas' discovery of the important role capital gains play in total return make this shortcoming more serious. Second, data were not utilized for stocks priced below $\$ 5.00$ per share, perhaps the most obvious class of 'low-priced' stocks. Finally, the sample sizes used for the study were extremely small for all price groups, causing one to question the general validity of his results. Recently, Heins and Allsion ${ }^{7}$ have further investigated factors affecting price volatility, with conclusions similiar to Clendenin's. However, they too used a quality classification scheme that eliminated non-dividend paying securities as well as irregular-dividend paying securities. Although their total sample size was greater than Clendenin's, the authors chose not to publish a breakdown of the sample by price classes. Consequently, one is unsure of both the absolute and relative size of each group. Also, there was never a statement of the authors definition of 'low-priced', and in order to investigate price volatility of differing price classes, explicit definitions of boundaries seem essential. Graham and Dodd, for example, have argued that low-priced could plausibly lie anywhere between zero and $\$ 20$ per share. ${ }^{8}$

The important aspect of these volatility studies in relation to
the present study is that a random group of low-priced stocks will, a priori, not possess the same quality as a random group of high-priced stocks. It is quite plausible that there may be little difference in volatitily when seperated into equivalent quality classes.

These studies have admittedly added to our knowledge of price behavior and potential rates of return available from investments in common stock but, at the same time, leave much unanswered and unexamined. Specifically, what are the rates of return from portfolios of common stock priced at $\$ 5$ or less; the role of dividends, stock splits or commissions in this price group's performance characteristics, or; the significance of the timing factor in achieving a given rate of return from low-priced securities.

## Purpose

The primary purpose of this study is to ascertain historical rates of return available from portfolios of low-priced common stocks (less than $\$ 5$ per share) selected from the American Stock Exchange during the years 1965-1969. These rate of return data will also be supplemented with information regarding the level of dividends received, the impact of transaction costs, portfolio sizes encountered, total investments required as well as other varied data of interest to investors.

It should be emphasized here that the approach is descriptive rather than normative, that is, no attempt has been made to differentiate between either the low-priced securities selected or the level of investment in each of these securities in order to optimize returns. It is hoped, however, that the foundation provided herein will speed the development of such a normative approach through, perhaps, the
application of fundamental and technical analysis to portfolios of lowpriced common stock. Investigations of performance characteristics and price behavior of differing price classes are also sorely needed in order to facilitate the comparison of the returns-this study furnishes a foundation for such investigations as well.

## Scope and Methodology

All securities included in the study were listed on the American Stock Exchange and initially priced at or below $\$ 5$ per share when selected. During the time periods examined, the 20 quarters from January 1, 1965 through January 1, 1970, a total of 386 such securities were included in the sample. From these, portfolios of varying size were generated by selecting those stocks priced at or below $\$ 5$ per share on the first trading day of the initial quarter while in subsequent quarters stocks are added to the original portfolio if: (l) they were previously unlisted and are currently selling at or below \$5, or (2) they were previously listed but selling above $\$ 5$ per share and are currently selling in the $0-\$ 5$ price range. Stocks may be dropped from a portfolio in subsequent quarters only if they are: (1) delisted from the American Stock Exchange (unless simultaneously moving to the New York Stock Exchange); (2) the non-surviving company in an acquisition or merger, or; (3) prevented from trading for a variety of reasons including being called, suspended, or liquidated.

The returns from these particular securities are then evaluated on the basis of three different portfolio models. The first, the Fixed Investment Model, assumes a $\$ 1000$ investment in each security in the initial quarter as well as a $\$ 1000$ investment in stocks added in
subsequent quarters. The second model, the Average Investment Model, assumes the same $\$ 1000$ initial investment; however, the investment in subsequent quarters is equal to the average investment in each security in the portfolio at that time. Third, the Fixed Investment Proportion Maintenance (FIPM) model also assumes the identical \$1000 initial investments. An intraportfolio reallocation of these investments is conducted at the end of each quarter so that each security represents the same proportion of the total portfolio value. Any new investments then have this dollar proportion invested in them. All portfolios recognize commissions and assume both a tax-exempt status and non-reinvestment of dividends.

## Organization

Following this introductory chapter are two chapters dealing with the study's methodology. Chapter II discusses the methodology employed for determination of time periods, portfolio selection, data collection and handling, and measurement of rate of return. Chapter III, in turn, examines each of the three portfolio models employed as well as the treatment of portfolio disposition in the terminal quarter.

The rate-of-return results for each of these portfolio models are then presented in Chapter IV, along with pertinent supplemental data dealing with portfolio sample sizes encountered, total dividends received, total commissions required and others. Finally, Chapter VI will present the conclusions of the study.

## Limitations

The primary limitation present in the study is due to the time
periods examined. It may well be unadvisable to generalize the rate-of-return data presented to time periods of differing length or market conditions. This limitătion may only be removed through future research in the area. The second limitation involves the restriction of the universe to the American Stock Exchange. It is quite conceivable that differing results would be discovered if one examined securities listed on regional exchanges or traded in the over-the-counter market. Lastly, the assumption of tax-exempt portfolios and non-reinvestment of dividends may be a limitation. Fisher and Lorie's results demonstrate that the investor's tax status has a significant effect on rate of return achieved, as does the reinvestment of dividends. It may well be, however, that the non-reinvestment of dividends is less a factor in this particular study for the majority of securities examined will, a priori, not be a dividend-yielding security except, perhaps, over long periods of time.

## METHODOLOGY OF THE STUDY-I

This study requires a somewhat extensive explanation of the methodology employed, primarily due to the large number of variables examined. To facilitate this explanation, this chapter will concern itself with those aspects of the methodology which are independent of a particular portfolio model, while the subsequent chapter will be devoted to the methodology of the portfolio models themselves.

## Time Periods Examined

The particular time periods chosen span the years from January, 1965 to January, 1970, with each interim quarter representing one time period. Thus, a total of 20 quarters, four in each of the five years, form the basic time periods. Quarter 21 (January, 1970) will always be the termination quarter for portfolios not terminated in a previous quarter. Furthermore, with each of the 20 quarters representing a possible initiation period or termination period, there exists some 210 combinations of time periods. To illustrate, suppose the initiation period was quarter 1 in 1965. The termination period could then be quarter 2, 3, 4, . . ., $21=20$ combinations: If quarter 2 in 1965 was the initial period, the termination period could then be quarter 3, 4, 5, . . ., $21=19$ combinations and so on. These particular years were chosen to facilitate data collection and to provide an analysis of
performance in a current environment.

## Criteria for Portfolio Selection

The various portfolios examined in the above time periods are all initially formed by selecting common stocks listed on the American Stock Exchange which are priced at or below $\$ 5.00$ per share without regard to such factors as quality, number of shares outstanding, earnings, priceearnings ratio or any variable other than price. In the event a particular stock was not traded on the first trading day of the initial quarter, it is still included in the portfolio if the asked price is at or below $\$ 5$ per share, or the arithmetic mean of the bid and asked price is at or below $\$ 5$. The study also makes the simplifying assumption of permitting fractional shares to be bought. The impact of this particular assumption will be tested, however, by examining the returns from one of the portfolio models while permitting only whole shares to be purchased. Tables will be introduced later which point out the difference in achieved rates of return under the two assumptions. With this one exception, a $\$ 1000$ investment is made in each security in the initial quarter regardless of the particular portfolio model being employed. Purchase commissions will, of course, make the actual investment per security somewhat higher than exactly $\$ 1000$. To illustrate, for those portfolios initiating in quarter 1 of 1965, a portfolio is generated comprising 278 common stocks. The total initial portfolio investment required would then be $278 \times \$ 1000$ plus brokerage commissions.

In subsequent quarters, prior to termination, additional stocks are added to the portfolio if: (1) they are stocks which were not listed on the American Stock Exchange in prior quarters, but have since
become listed and are currently priced at or below $\$ 5$ per share, or; (2) if they are stocks which have been listed in prior quarters, were previously selling above $\$ 5$ per share, but are currently in the $0-\$ 5$ price range. The size of the investment in these new securities is a function of the portfolio model being employed. Once a particular stock is added to the portfolio it is retained until the termination period unless: (1) the stock is delisted from the American Stock Exchange and is not moving to the New York Stock Exchange; (2) the stock is being acquired or is the non-surviving firm in a merger, or; (3) the stock is prevented from trading for a variety of reasons such as being halted, suspended, liquidated, or called.

The treatment of securities that are disposed of prior to the termination period follows a general procedure. For stocks involved in a merger, liquidated, or called, the closing quote on the final day of trading is taken as the selling price; however, the cash inflow from the sale is assumed to occur at the end of the quarter. For any particular quarter, both the absolute number of stocks in these catagories and the discrepancies in timing of cash flows are not significant enough to create distortions in the rate of return.

For stocks delisted, halted, or suspended, the information of such action is assumed unavailable until after the fact. Prices are then taken from the over-the-counter market. If a price range was available for the first month after the action the monthly low bid price is used as the selling price; if no such price is available in the first month, the same procedure is employed for the second and third months. All cash inflows are again assumed to occur at the end of the quarter during which the price is obtained. In the event no price quote is
available at the end of three months, the security is assumed to be a complete loss and a price of $\$ 0$ is recorded as the final selling price with no commissions being charged for the disposal of these valueless securities.

## Data Collection

For each of the 386 securities included in the study, data were collected to enable the valuation of portfolios and determination of rates of return. Specifically, price data were obtained on a quarterly basis from the ISL Stock Price Indices ${ }^{1}$ for January 1, 1965 through January 1, 1970. The price recorded was the closing price on the first trading day of each respective quarter with the noted exception of prices being recorded for stocks being dropped from the portfolio.

Since the price quotes were affected by stock splits, reverse splits, and stock dividends, it was necessary to accumulate data on these factors. Standard and Poor's Annual Dividend Records ${ }^{2}$ for 19651969 were used as the reference source for such data. For ease in computer handling of the data, all figures were recorded as stock dividends, that is, a 2 -for-l stock split would be recorded as a 100 percent stock dividend and a l-for-5 reverse split would be recorded as a -80 percent stock dividend.

Although cash dividends were not assumed to be reinvested, quarterly data on such cash dividends were collected, again from Standard and Poor's Annual Dividend Records, ${ }^{3}$ to enable the comparison of the absolute and relative size of such dividends to the size of transaction costs. The ex-dividend date was used as the date the dividend was paid and all cash inflows were assumed to occur at the end of the respective
quarter in which the ex-dividend date fell.
The only other data required consisted of the particular quarter number in which the securities were sold because of mergers, delisting, etc. These were collected from the ISL Stock Price Indices 4 and/or Standard and Poor's Stock Guides。 ${ }^{5}$ As mentioned previously, all securities not sold prior to January 1,1970 were assumed to be sold at that time.

## Brokerage Commissions

All portfolios, regardless of the particular model, incorporate transaction costs for both purchasing new securities or selling securities from an existing portfolio. Brokerage commissions were calculated based on the following formulae:

Round Lots-100 shares

| Price Between | Commission |
| :--- | :--- |
| $\$ 0-\$ 1$ | $\$ 6$ |
| $\$ 1-\$ 4$ | 2 times price of 1 share $+\$ 3$ |
| $\$ 4-\$ 24$ | Price of 1 share $+\$ 7$ |
| $\$ 24-\$ 50$ | $\frac{1}{2}$ Price of 1 share $+\$ 19$ |
| $\$ 50$ and over | $1 / l 0$ of price of 1 share $+\$ 39$ |
| Maximum of $\$ 75$ per round lot and minimum of $\$ 6$. |  |

Odd Lots

| Amount Involved | Commission |
| :--- | :--- |
| $\$ 0-\$ 100$ | $\$ 6$ |
| $\$ 100-\$ 400$ | $2 \%$ plus $\$ 1$ |
| $\$ 400-\$ 2,400$ | $1 \%$ plus $\$ 5$ |
| Maximum of $\$ 75$ and minimum of $\$ 6$. |  |

Again, if the selling price of a security was assumed to be zero, no commissions were charged the portfolio for the elimination of holdings in the security. Also, if the price is under $\$ 1.00$ (round iot) or the amount involved is less than $\$ 100$ (odd lot), commissions are generally mutually agreed upon. On trades of this type a $\$ 6.00$ brokerage fee was assumed even though some, but not all, brokerage firms have recently raised their minimum commission to $\$ 15.00$.

## Measurement of Rate of Return

The method employed to measure portfolio rates of return is of some importance to the validity of a study of this nature. If a portfolio experiences no contributions or withdrawals of capital subsequent to initial investment, the measurement of rate of return over a specified period of time is relatively simple, For example, given a begine ning investment cost ( C ) of $\$ 100$ and ending portfolio value (V) of
$\$ 106.70$, the percentage return can be computed by (V/C) $-1=6.7 \%$. Converting this percentage into an annual rate of return, the formula becomes $(V / C)^{1 / y}-1$, where $y$ is the time period expressed in years. In more general terms, $V=C(1+r)^{y}$, where $r$ is the annual rate of return compounding annually.

Unfortunately, two factors eliminate the feasibility of employing this technique: (1) the portfolio is subject to additional contributions or withdrawals of capital during the time periods used in this study, and (2) the portfolio manager is assumed to have no influence over either the timing or the amount of contributions to or withdrawals from the portfolio.

One must also recognize that measurement techniques based on arithmetic combination of percentage changes may be misleading, for this method assigns greater weight to increases than to decreases. For example, a stock declining from $\$ 5.00$ to $\$ 4.00$ and subsequently returning to $\$ 5.00$ would have experienced consecutive percentage changes of -20 percent and +25 percent. Arithmetic combination would have produced $a+5$ percent-melearly misrepresentative of the actual percentage change! Robert Levy ${ }^{6}$ has suggested an approach which recognizes and accounts for all the factors discussed above. The approach, termed 'unit accounting', will be utilized throughout the study when computing annualized rates of return. This technique may best be explained with the aid of an illustration adapted from Levy. It is assumed that the portfolio is initially invested in 100 units, each with a value of \$1.00. The portfolio value per unit is determined prior to each contribution or withdrawal, and again at the end of the period. Thus, it is possible to express contributions and withdrawals in terms of portfolio

PORTFOLIO

| Time <br> Periods | Beginning <br> Value | Ending <br> Value | Value <br> Per Unit |
| :---: | :---: | :---: | :---: |
| 1 | $\$ 100$ | $\$ 106$ | 1.060 |
| 8 | $(50)$ | 110 | 1.100 |
| 9 |  | 50 | 0.917 |
| 18 | 250 | 30 | 0.733 |
| 19 |  | 330 | 0.809 |
| 24 |  | 0.835 |  |

units and to use these units in the computation of ending value on a per unit basis. The assumed number of initial units is immaterial. The measurement of return is based upon the relationship between beginning and ending value per unit and for any given portfolio, this relationship is independent of the initial units assumed.

The cumulative unit value ( $R$ ) is determined by division of the ending unit value ( $V_{n}$ ) by the initial unit value ( $V_{o}$ ), that is, $R=V_{n} / V_{0}$. The annualized compound rate of return ( $r$ ) may then be determined by solving the equation:

$$
r=R^{1 / y}-1
$$

where $y$ is the length of the time period, expressed in years. In terms of the above illustration, the annualized compounded rate of return from period 1 to period 24, assuming the length of each period to be one month, would be determined by:

$$
\begin{aligned}
& R=\frac{V_{24}}{V_{0}}=\frac{0.835}{1.000}=0.835, \text { and } \\
& r=0.835^{\frac{1}{2}}-1=-8.6 \text { percent }
\end{aligned}
$$

If the same $R$ had been obtained in a period of three months ( $\frac{1}{4}$ of a year) the annualized rate of return would then be given by:

$$
r=0.835^{1 / \frac{1}{4}}-1=0.835^{4}-1=-51.4 \text { percent }
$$

This technique is thus quite capable of permitting the investigation of annualized compounded rates of return for the basic quarterly (3 months) time periods utilized in the study as well as simultaneously removing the deficiencies of an arithmetic determination of rates of return.

## METHODOLOGY OF THE STUDY--II

In this chapter the methodology of the particular portfolio models and valuation strategies are examined. The portfolio models employed are two varieties of the traditional buy-and-hold model, the Fixed Investment model and the Average Investment model, and a portfolio model recently proposed by Evans ${ }^{1}$--the Fixed Investment Proportion Maintenance Model (FIPM). Portfolio valuation strategies are defined as either cash-to-portfolio or cash-to-cash.

The large number of variables present in the various models and strategies makes it desirable to provide definitions in one location so as to facilitate discussion and aid comparisons. The following definitions are employed:

GPV--Gross portfolio value
NPV--Net portfolio value
GPI-Gross portfolio investment
NPI--Net portfolio investment
S-Total sales proceeds
PS-Portfolio adjustment sales
PP--Portfolio adjustment purchases
Cp-Total commissions on purchases
Csm-Total commissions on sales
Cpp-Total commissions on portfolio adjustment purchases

```
Cps--Total commissions on portfolio adjustment sales
    A--Average investment per security
    X--The number of shares owned for any security
    O-_Price per security
    N-Number of securities in a portfolio
    P--Number of securities purchased
    S-Number of securities sold
```

## Fixed Investment Model

The fixed investment portfolio model invests an equal $\$ 1000$ in each security, regardless of the acquisition quarter, plus purchase commissions. The decision rule is: in the first quarter when the portfolio is formed invest $\$ 1000$ in all securities priced at or below $\$ 5$ per share. If in a subsequent quarter another stock, not presently held, is selling at or below $\$ 5$ per share invest $\$ 1000$ in this security. Hold all securities until the entire portfolio is liquidated. The initial (i) gross portfolio investment is:

$$
\begin{equation*}
\mathrm{GPI}_{i}=\mathrm{p}(\$ 1000)+\mathrm{Cp} \tag{1}
\end{equation*}
$$

The net portfolio investment (after sales) at the end of a quarter is:

$$
\begin{equation*}
N P I_{t+1}=G P I_{t}-(S+C s) \tag{2}
\end{equation*}
$$

The gross portfolio value in any quarter after the first is thus:

$$
\begin{equation*}
\mathrm{GPI}_{\mathrm{t}+1}=\mathrm{NPI}_{\mathrm{t}+1}+\mathrm{p}(\$ 1000)+\mathrm{Cp} \tag{3}
\end{equation*}
$$

or

$$
\begin{equation*}
G P I_{t+1}=G P I_{t}-(S+C s)+p(\$ 1000)+C p \tag{4}
\end{equation*}
$$

The value of $S$ in (2) and (4) above represents, for this model, the before-commissions liquidation proceeds for securities being sold due to mergers, delistings, etc.

## Average Investment Model

The second portfolio model, the Average Investment Model, assumes the same initial \$1000 investment. However, subsequent additions to the port folio may require more or less than the $\$ 1000$ investment depending on the portfolio value at the time the new investment is made. The decision rule for this model is: in the first quarter when the portfolio is formed invest exactly $\$ 1000$ in all securities priced at or below $\$ 5$ per share. In subsequent quarters the investment for new securities equals the average value per security in the present portfolio. Thus, if a portfolio of 20 stocks is currently valued at $\$ 30,000$ any current additions require an initial investment of $\$ 30,000 / 20$, or $\$ 1500$. In this model as in the Fixed Investment Model, all securities are held until the entire portfolio holdings are eliminated.

The initial (i) gross portfolio investment is:

$$
\begin{equation*}
\mathrm{GPI}_{i}=p(\$ 1000)+C p \tag{5}
\end{equation*}
$$

To derive gross portfolio investment (after the first quarter) for the Average Investment Model it is necessary to value the portfolio at the end of the quarter. The gross portfolio value at the end of a quarter is given by:

$$
G P V_{t+1}=\sum_{k=1}^{n}\left(X_{k} \cdot O_{k}\right)
$$

The net portfolio value (after sales) is derived by:

$$
\begin{equation*}
N P V_{t+1}=G P V_{t+1}-(S+C s) \tag{7}
\end{equation*}
$$

Thus, after sales, the average investment per security is:

$$
\begin{equation*}
A_{t+1}=N P V_{t+1} /(n-s) \tag{8}
\end{equation*}
$$

The gross portfolio investment (for any quarter after the initial quarter) for the Average Investment Model is thus:

$$
\begin{equation*}
\mathrm{GPI}_{\mathrm{t}+1}=\mathrm{NPV}_{\mathrm{t}+1}+\mathrm{p}(\mathrm{~A})+\mathrm{Cp} \tag{9}
\end{equation*}
$$

where $N P V_{t+1}$ is given by (7) above and $A_{t+1}$ is derived by (6), (7), and (8) above. The difference between the Fixed Investment Model and the Average Investment Model may be seen by examining (3) and (9) above.

Over a period of quarters it is possible for the gross (and net) portfolio investment for the Average Investment Model to be above or below that required by the Fixed Investment Model depending on whether the market is rising or falling. Under either of these two models, the number of stocks and total capital required fluctuates in relation to the number of new additions and the number of stocks sold because of delistings, mergers, etc.

Fixed Investment Proportion Maintenance Model

In a recent article John L. Evans ${ }^{2}$ contends that the buy-and-hold criterion is not an adequate standard of comparison for portfolios of securities.

However, when the investigation is concerned with portfolios of securities this criteria is not sufficient-that is, the buy-and-hold strategy is no longer the appropriate standard against which to measure the performance of alternative policies. It will be shown that a mechanical trading rule exists which, when applied to portfolios of securities consistently leads to significantly greater expected returns than those produced by the naive buy-and-hold strategy. 3

The FIPM model involves an intraportfolio reallocation at the portfolio value so that each individual security possesses the same percentage value of the total. For example, if at quarter $t$ four securities
constitute equal investment in the portfolio, then at time $t+1$ (beginning of the next quarter) the portfolio would be reallocated so that the proportion invested in each security is maintained at 25 percent of the total portfolio value. In effect the investor follows a form of 'dollar averaging' by purchasing more shares of securities whose prices have fallen and selling shares of those securities whose prices have risen. According to Evans the FIPM model should yield superior returns to a buy-and-hold model.". . . if (l) there exists some intrinsic value of a security about which the market value fluctuates randomly and (2) the market is characterized by an inherent upward tendency over the long run." ${ }^{4}$

The decision rule for the FIPM is thus: in the first quarter when the portfolio is formed invest exactly $\$ 1000$ in all securities priced at or below $\$ 5.00$ per share. At the end of each quarter evaluate the portfolio and reallocate the individual security values so that each possesses the same percentage proportion of the total portfolio value. The investment in new additions to the portfolio in the subsequent quarter will then be the dollar equivalent of this common percentage. Again, the initial portfolio investment is given by:

$$
\begin{equation*}
\mathrm{GPI}_{i}=\mathrm{p}(\$ 1000)+\mathrm{Cp} \tag{10}
\end{equation*}
$$

And the net portfolio investment (after sales) at the end of a quarter is:

$$
\begin{equation*}
N P I_{i}=G P I_{i}-(S+C s) \tag{11}
\end{equation*}
$$

The remainder of the process becomes a bit more complex for the FIPM model due to ackwardness caused by brokerage commissions. The essence of the FIPM model is that the portfolio adjustment sales (PS) should be equal to the portfolio adjustment purchases (PP). Without
commissions this is simply:

$$
\begin{equation*}
P P=P S \tag{12}
\end{equation*}
$$

with the average investment (after adjustment) being exactly equal for all securities. However, with the inclusion of brokerage commissions the equation becomes

$$
\begin{equation*}
P S-C p s=P P+C p p \tag{13}
\end{equation*}
$$

so that the average investment is equal. It was found extremely difficult (but not impossible given enough computer time) to satisfy equation (13). Therefore, the requirement was established that equation (12) be fulfilled ( $\mathrm{PS}=\mathrm{PP}$ ) and then the commissions (Cps + Cpp) were added as a gross contribution. The gross investment, after the initial quarter, for the FIPM model is then given by:

$$
G P I_{t+1}=N P I_{t+1}+[p(A)+C p]+[-P S+P P+C p s+C p p](14)
$$ where $N P I_{t+1}$ is given by (11), A is given by (6), (7), and (8) and the portfolio adjustment is handled as outlined above. The gross portfolio investment necessary for the FIPM model therefore contains a slight upward bias (the sum of Cps and Cpp) that the buy-and-hold models do not contain.

In reality, one more minor adjustment was made in the FIPM model. Due to the high cost associated with making very small trades, portfolio rates of return were analyzed under three conditions in an attempt to quantitatively evaluate the impact of these small trades. The FIPM model was first permitted to make portfolio adjustments regardless of the dollar size of any trade; then the adjustments were permitted only if the dollar value of a trade exceeded $\$ 50$; then only if the dollar value of a trade exceeded $\$ 100$. Although tables will later present the returns achieved under each of the three conditions, the $\$ 100$
restriction-FIPM model demonstrates superiority even though equation (12) is not strictly fulfilled.

## Valuation Strategies

With regard to the portfolio models, two valuation strategies were utilized in determining portfolio values in the terminal quarter. In accordance with Fisher and Lorie's ${ }^{5}$ terminology, these are a Cash-toPortfolio strategy and a strategy and a Cash-to-Cash strategy. Both strategies retain the assumptions of tax-exempt portfolios and nonreinvestment of dividends.

## Cash-to-Portfolio

A Cash-tomPortfolio valuation strategy may be defined as the strategy by which the annualized, compounded rates of return are determined after interim payments of commissions on transactions involving an addition or deletion to the portfolio and retaining the portfolio, without liquidation, at the end of the terminal quarter. Under this strategy the $S$ term in equations (2), (4), (7), and (11) for the final quarter represents only the sale of securities being delisted, merged, etc., in that particular quarter.

## Cash-to-Cash

A Cash-tomash valuation strategy may be defined as the strategy by which the annualized, compounded rates of return are determined after interim payments of commissions on transactions involving an addition or deletion to the portfolio as well as payment of commissions for conversion of the entire portfolio holdings into cash at the end of the
terminal quarter. Under this strategy the $S$ term in equations (2), (4), (7), and (11) for the final quarter represents the sale of all stocks in the portfolio and the Cps term represents the commissions necessary for this liquidation of the portfolio, rather than securities being sold because of delisting, mergers, etc.

There are thus six possible combinations of portfolio models and valuation strategies by which to compute the rates of return: Fixed Investment Model—Cash-to-Portfolio; Fixed Investment Model—Cash-toCash; Average Investment Model-Cash-tomPortfolio; Average Investment Model-Cash-to-Cash; FIPM Model-Cash-tomPortfolio, and; FIPM Model-Cash-to-Cash. Each of these combinations are utilized.

## CHAPTER IV

## PRESENTATION OF RESULTS

In this chapter rates of return, dividends, and commissions data are presented, as well as supplemental statistics on portfolio sample sizes and cumulative portfolio investments required. The primary breakdown for presentation of rates of return will be cash-to-portfolio versus cash-to-cash (assuming, in the latter case, complete liquidation of the portfolios). In each of these catagories three situations will be examined: (1) the Fixed Investment Model; (2) the Average Investment Model, and; (3) the FIPM Model employing the $\$ 100$ minimum adjustment restriction, Deviations from this breakdown will occur, however, when the returns from portfolios possessing fractional shares are compared to returns from portfolios possessing only whole shares, and when returns are compared for the FIPM Model employing a zero, \$50, and \$100 adjustment restriction. Whenever possible ( e.g., for cumulative commissions), the presentation of the supplemental data will also follow this format; however, in some cases (e.g., for cash dividends) the differentiation between cash-to-portfolio and cashotomeash is unnecessary. For such data, tables are merely presented by portfolio model or, if even this differentiation is unnecessary (e.g. portfolio sample sizes) as a common, all-encompassing table. While the results of the supplementary data are analyzed herein, the actual tables for such data are presented in Appendix B.

The tax-exempt cash-to-portfolio returns are presented in Tables I, II, and III. The annualized, compounded rate of return for any quarter, or combinations of quarters, may be determined by selecting the initial quarter from the vertical column and moving horizontally to the desired termination quarter. For example, if the initial quarter was April, 1965 (1965-2) and the termination quarter was July, 1968 (1968-3) the rate of return, compounded annually, would be 53 percent. The first diagonal row indicates the returns on all portfolios of only one quarter in duration and, because of the identical initial $\$ 1000$ investments, are the same returns regardless of the portfolio model chosen.

An examination of these tables indicate, first, the fairly high, positive rates of return achieved for most holding periods except portfolios formed in 1969. While data indicating the rates of return for all stocks listed on the American Stock Exchange are unavailable, the average price of a share of stock (the American Stock Exchange index) is known. Compared with the price on January 1, 1965, the average price at January 1, 1966 and 1967 had increased about 40 percent, as of January, 1968 about 140 percent, and by 1969 about 200 percent. Note that these percentages are neither annualized nor compounded. For most comparable time periods the portfolio rates of return (for all three models) exceeded the returns on an average share of stock on the American Stock Exchange. Although unavailable at the present time, rem turns for this 1965-1969 time period from Fisher and Lorie's study ${ }^{1}$ should provide interesting comparisons.

The second factor shown by the tables is the extreme volatility in

TABLE I

CASH-TO-PORTFOLIO ANNUAL RATES OF RETURN--FIXED INVESTMENT MODEL

| 19691 |  |  |  |  |  |  |  |  |  |  |  | $\sim$ |  |  |  |  | -41.3 | -47.2 | -46.6 | -53.6 |
| 19692 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | -56.6 | -31.1 | -41.7 |
| 19693 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | -49.4 | -41.2 |
| 19694 |  |  |  |  |  |  |  |  |  | $\therefore$ |  |  |  |  |  |  |  |  |  | -31.6 |

portfolio returns. Note that the level of returns range from a -64.6 percent to a positive 347.7 percent. Most of the volatility also appears in the earlier quarters while returns stabilize somewhat over the longer time periods. Third, both of the buy-and-hold models' rate of returns were closely similiar. Excluding the first diagonal row, leaving 190 quarter combinations, the Average Investment Model and the Fixed Investment Model Returns were within 0.1 percent of each other 90 times, and were within 0.5 percent 180 of the 190 combinations. The Fixed Investment Model does, however, appear to possess a consistent, though mild, superiority for in the 100 combinatons differing by more than 0.1 percent, the Fixed Investment Model's return is higher for 93 combinations, with the Average Investment Model outperforming the Fixed Investment Model in only 7.

The general superiority of the FIPM Model (as compared with the Fixed Investment and Average Investment Models) is also demonstrated. Again eliminating the first diagonal row, returns from the FIPM Model exceeded the returns from both of the other models 150 times, often by 6 percent or more. Note also that of the 40 times the returns from the FIPM Model were not superior, 12 of these were in the immediate quarter after initiation of the portfolio, indicating the FIPM Model becomes more superior than the other models with time. In general, these find ings support some earlier findings that timing is essential in determining rates of return, and that portfolio returns tend to stabilize over longer time periods.

## Cash-to-Cash Portfolio Rates of Return

Tables IV, V, and VI present cashotomash rates of return for the
three different models. The same relative tendencies found in Tables I, II, and III are also evident in these tables. The impact of final brokerage commissions on the absolute rates of return, however, is, in some cases, very substantial. For example, the rate of return for the Fixed Investment Model for the period $1965-1$ to $1965-2$ was 84.3 percent under a cash-tomortfolio valuation strategy, while it was only 6 l. 5 percent under the cash-tomcash assumption. However, for longer time periods the differences decrease, and in many cases the rates of rew turn (for the two situations) differ by as little as 0.1 to 0.4 percent. This provides ample evidence of the importance of commissions (both in and out) on common stock returns, particularly when returns on low-mpiced common stocks are examined.

## Portfolio and Stock Characteristics

The relatively high portfolio returns presented in Tables I through VI coupled with the variability of returns requires further examination. Inorder to evaluate why these results occurred, the following are examined: (1) total portfolio size; (2) total portfolio investment; (3) total portfolio commissions and cash dividends, and; (4) some characteristics of the low-priced common stocks forming the portfolios.

Total Portfolio Size

The number of securities included in various portfolios was by no means constant over the time periods. It should be noted, however, that the respective portfolio sample sizes are identical for the three models (under either the cash-tomportfolio or cash-tomeash valuation

strategies). The inconsistency in portfolio sizes was due in large part to the general increase in market prices of stocks listed on the American Stock Exchange during the 1965-1969 period. While stock prices declined in 1969, the general increase in prices during prior years meant that fewer securities were trading in the $0 \times \$ 5$ price range. Table VII indicates all new portfolios formed after the thrid quarter of 1967 con tained less than 100 securities and all new portfolios (except 1969-4) formed after the third quarter of 1968 contained less than 50 securities (In interpreting Table VII it is important to remember that securities may enter into the portfolios after the initial quarter, but may not be sold except for mergers, delistings, etc.). The number of securities included in the porfolios ranged from a high of 341 to a low of seven. Due to the relatively small portfolio sizes in 1968 and 1969, there is somewhat less confidence in these returns being indicative of returns from low-priced stocks during this time period.

Portfolio Investment Levels

Not only is the number of securities subject to change, but the three models also require different total dollar investments. Supplem mental Tables $I$, II, and III (see Appendix B) present the cumulative investment required for the Fixed Investment Model, Average Investment Model, and FIPM Model, respectively, The smallest investment for any of the quarter-combinations was $\$ 7200$, while the largest cumulative in vestment was $\$ 386,000$. The first diagonal row is again the same for all three models. In general, the FIPM Model required the largest investment, the Average Investment Model required less than the FIPM Model, and the Fixed Investment Model required the least. This occurred,

in large part, because the Average Investment and FIPM Models often rem quired initial investments in excess of $\$ 1000$ for securities purchased subsequent to the initial quarter. In addition, the FIPM Model required even greater investment due to treatment of commissions necessitated when intraportfolio adjustment occurred (See Chapter III, equations (12), (13), and (14).

## Brokerage Commissions and Cash Dividends

Supplemental Tables IV through IX (Appendix B) present the cumulative brokerage commissions for the three models under the cashotom portfolio and cash-tomeash strategies, respectively. The amount of cash dividends received are then shown in Supplemental Tables X, XI, and XII (Appendix B). Under the cashotomortfolio strategy, with only nine exceptions (in 210 periods) cumulative commissions exceeded cumulative dividends in the Fixed Investment Model; in the Average Investm ment Model there were eleven exceptions, and; in the FIPM Model, commissions were considerably larger than dividends in all 210 periods. However, for both the Fixed Investment and Average Investment Models, the slope (when graphed) of the ${ }^{\text {odividends curve }}$ appears to be greater
 quired for the former to overtake the latter. No such statement can be made for the FIPM Model. In the cashotomeash situation, commission charges (for all models) always exceeded cash dividends.

An aggregrate comparison actually understates the magnitude of the difference if the time value of money is recognized. While most commio sion charges were incurred early in the portfolios, dividends tended to flow in more rapidly as the length of the period was extended. The
relatively low level of cash dividends to brokerage commissions was primarily due to: (l) relatively higher brokerage charges on low-priced common stocks than on higher priced stocks and (2) the fact that only 125 (out of 386 ) stocks paid any cash dividends during the examination period.

## Characteristics of the Low-Priced Stocks

The characteristics presented in this section include: (1) the stocks that had to be sold and (2) the relationship between the initial purchase price and the maximum (highest) price attained. One hundred and six stocks had to be sold or dropped from the portfolios. Table VIII indicates that 40 stocks disappeared because of mergers, one was

${ }^{\text {a }}$ Time period is not the same for all stocks.
price of stocks included in the portfolios and the highest price during the period examined. The percentage increases for many of the stocks ranged as high as 2000 to 4000 percent. However, eighteen stocks
included in the portfolios never rose above their purchase price. Note, too, that the time periods over which these changes occurred are not the same for all stocks. Many of the securities first bought in latter 1968 or in 1969 are described in the lower columns. Given more time these may or may not have experienced larger percentage changes. In general these findings indicate that, under favorable circumstances, it is not unusual for many low-priced stocks to increase in excess of 300 percent during the 1965-1969 time period.

## FIPM Adjustment Restrictions

As mentioned earlier, the FIPM Model whose rates of return are presented in Tables III and VI employed a $\$ 100$ minimum adjustment restriction. This model was initially tested, however, with both no restriction and again with a $\$ 50$ trading restriction. The results of these tests are presented in Appendix B, as Supplemental Tables XIII, and XIV. While the difference in returns for the $0-\$ 50-\$ 100$ restrictions were occasionally negligible, the consisent overall superiority of the $\$ 100$ restriction prompted its use. Additional investigation of intraportfolio adjustment procedures remains needed however. The particular restrictions tested were arbitrarily selected and differing restrictions could quite conceivably improve the model.

Whole Versus Fractional Shares

Another simplifying assumption made in the study was the allowance of fractional share purchases when investing in securities. Due to the limited number of transactions in the Fixed Investment and Average Investment Models this assumption is less critical than for the FIPM

Model. Consequently, a test run was made using the cash-to-portfolio FIPM Model (with the $\$ 100$ restriction) which permitted only whole shares to be purchased. Supplementary Table XV in Appendix B presents the rates of return for the whole-share assumption. It appears that the returns, while often similiar, are generally somewhat higher than those from the fractional share run. Consequently, the rates of return presented in Tables III and VI (FIPM Model) may be slightly upward biased.

## CHAPTER V

## CONCLUSIONS

The primary purpose of this study was to ascertain historical rates of return from portfolios of low-priced stock listed on the American Stock Exchange during 1965 to 1969. In addition the study examined the impact of transaction costs, receipt of dividends, portfolio sizes, and required portfolio investments along with supplementary characteristics of the low-priced stocks themselves. Returns were presented for three different portfolio models on both a cash-to-portfolio and a cash-tom cash basis.

The major findings of the study may be summarized as follows. First, the annualized, tax-exempt rates of return on portfolios of lowpriced stock were fairly high and positive although portfolios formed during the last year of the study (1969) produced negative rates of return. Second, the rates of return exhibit extreme volatility. The returns ranged from 347.7 percent to -64.6 percent for the cash-toportfolio strategy, and from 306.1 percent to -69.5 percent for cash-tocash portfolios. Negative returns were found in approximately twentyseven portfolios (out of 210).

All models were based on the basic decision rule of adding, each quarter, all stocks that met the $0-\$ 5$ criteria. In general, the most superior returns were yielded by the FIPM Model, with the two buymandhold models, Fixed Investment and Average Investment, yielding quite
similiar returns to each other. The same pattern occurred even after inclusion of brokerage commissions in the FIPM Model. Further research is needed on how to effectively integrate brokerage commissions into the FIPM Model. This is particularly true when the intraportfolio adjustments are made at the end of each quarter. The $\$ 100$ minimum trading range employed in this study means that portfolio adjustment purchases will not, in general, equal portfolio adjustment sales. Accordingly, net contributions (to the gross portfolio investment) or net withdrawals are required each quarter for the FIPM Model.

Cash dividends were usually much less than commissions for all 3 models on either a cash-to-portfolio or cash-to-cash basis. For the buy-and-hold models, however, dividends begin to compensate for the commissions after approximately l8-20 quarters. The impact of brokerage commissions themselves on the cash-tomeash returns was substantial for short holding periods, but diminished over longer periods.

Of the 386 stocks included in the study, 106 had to be disposed of and 32 (of the 106) were assumed a complete loss. These figures are indicative of the susceptability of low-priced stocks to merger, delisting, or liquidation. Many stocks, however, experienced considerable appreciation in price. Some 202 (of 386) securities increased above the initial purchase price by 300 percent or more, with 40 stocks increasing greater than 1000 percent, and 20 more than 2000 percent. Additional research may be quite helpful (and perhaps quite profitable) in segregating these high-potential securities from those which do not appreciate in value. Some additional suggestions for further research are also provided. First, the FIPM Model needs considerable investigation both in the role of dividends as well as adjustment commissions. The superior returns of
this model suggest that research may be more rewarding here than for the traditional buy-and-hold models. Second, examination of differing time periods and market environments are required to discover if the returns presented in the study are representative. Along these same lines, the study of low-priced stocks from other exchanges and the over-the-counter market would provide valuable comparisons of returns. Lastly, thorough, historical studies of rates of return from stocks in other price classes are now needed. The investor will then be able to objectively evaluate potential return from a low, medium, or high-priced common stock investment.

It is appropriate to conclude with a caveat: In this study, as in others attempting to measure investment performance, a number of assumptions are required. First a time period must be selected. Next, investment models or procedures must be specified. Finally, a decision has to be made on the treatment of commissions and dividends. The problems were carefully considered (especially with reference to the FIPM Model) and what seemed reasonable assumptions were made. While others might wish for slightly different assumptions, confidence is expressed in the basic accuracy and validity of the results.

## APPENDIX B

## SUPPLEMENTARY DATA TABLES

This Appendix contains tables for that data considered supplementary to the rate of return figures. Tables I through III present the cumulative investment required for each of the three portfolio models. Tables IV through IX list the cumulative brokerage commissions paid for each of the models under both the cash-to-portfolio and cash-to-cash strategies. The cash dividends received by the models are contained in Tables X, XI, and XII. Both Tables XIII and XIV give rate of return figures for the FIPM Model--the former for no restrictions on adjustments and the latter for a $\$ 50$ restriction. Lastly, Table XV presents the rates of return for the FIPM Model which restricted the $\$ 1000$ security investments to the nearest whole share.

SUPPLEMENTAL TABLE I
