## ACKNOWLEDGEMENTS

The writer $1 s$ especially indebted to Dr. Henry R. Angelino, chairman of the dissertation committee, for his encouragement and guidance throughout the doctoral program. Profound indebtedness is also extended to Dr. Omer J. Rupiper for his thoughtful help and enlightened suggestions. The writer also wishes to express his appreciation to Drs. Herbert R. Hengst and Chipman G. Stuart for their understanding and encouragement. To Dr. Paul Unger, who served on the committee during most of the program, the writer owes a great debt.

Valuable advice and assistance has been received from Dr. Gerald T. Kowitz, Dr. Mohammed V. A. Khan, Mr. Edward H. Ritter, Dr. and Mrs. Kenneth L. Loewen, Mr. Denzil R. Porterfield, and many others. To the students who participated in the study as subjects, the writer expresses his special thanks for their cooperation.

A special kind of indebtedness, deeply felt, is to my wife, Himi, for her sacrifice, endurance, and encouragement. without her understanding and spiritual support this study woula not have been possible.

## CHAPTER I

## THE PROBLEM

## Background and Need for the Study

Contemporary society is rapidly changing and tending toward greater complexity in all facets of human life. Never before in history has man's thinking been so challenged; neither has he been so constantly confronted with controversial issues and propaganda. While diverse ideas must be tolerated, it is apparent that a democracy can be sustained only when its citizens are able to exercise the higher thought processes and judge pertinently and discriminatingly. Therefore, development of the ability to think critically is generally recognized as an essential attribute of any citizen in a democratic society. With regard 亡o its importance, the Eduoational Policies Commission had this to says

The rational powers of the human mind have always bsen basic in establishing and preserving freedom. In furthering perconal and social effectiveness they are becoming more important than ever. They are central to individual dignity, human progress, and national survival.

The purpose which runs through and strenthens all other educational purposes--the common thread of edu-cation--is the development of the ability to think

Dewey (15) insisted that the intellectual aspect of education consisted of the formation of "wide-awake, careful, thorough habits of thinking." To him, the business of education was therefore to:

#### Abstract

cultivate deep-seated and effective habits of discriminating tested belief from mere assertions. guesses, and opinions; to develop a lively. sincere. and open-minded preferencs for conclusions that are properly grounded, and to ingrain into the individualis working habits methods of inquiry and reasoning appropriate to the various problems that present themselves.

Although critical thinking is generally regarded as one of the most important educational aims, there is abundant evidence which indicates that progress toward this goal has been quite slow. Taba (61) pointed out that little had been done in developing critical thinking in adolescents and young people. Good (28) likewise critized that the schools' demands for conformity accounted for the lack of progress. In recent years, development of thinking continues to be neglected in the school curriculum. (52)

Slow progress in the improvement of critical thinking habits is also reflected by the dearth of research in this area. Bnnis (23) estimated that on the average, less than two studies a year are published on this topic. Russell (55) knew of no book in child psychology that devoted a chapter to critical thinking. Signori (59) pointed out that personality and critical thinking are not frequently related to one another in the psychological literature. He insisted that
there is an essential dependency of thinking upon personality processes. The lack of improvement in thinking, acoording to hin, can be ascribed to the little concern for influences of personality factors. A lack of suitable devices to measure critical thinking was suggested by Edwards (19) to account for the slow improvement in thinking ability.

More research needs to be done with regard to the improvement of critical thinking. The present investigation is an attempt to meet this demand.

## Justification of the Study

The institution at which the present study was conducted was concerned with strengthening the effectiveness of its general education program as well as with the improvement of its remedial program. This necessitated identification of those factors which hinder or facilitate the teaching and learning processes. Since thinking is essential to learning, the quality of critical thinking of the students and its relationship to other variables was subjected to investigation.

An overview of related literature revealed that no study pertaining to critical thinking has been made using Negro subjects. The extent to which most of the research findings could be generalized to Negro students wight be very limited in view of the substantial differences in cultural and educational background that characterize the Negro population. of extreme importance is that test norms relevant to
the Negro population were not always available. Consequently, the results of such research may not always be interpreted without special provisions and reservations. It follows that norms should be provided and developed in order that a meaningful interpretation of test scores and research results may be achieved.

The Hatson-Glaser Gritical Thinking Appraisal was found to be a widelj used instrument both for the purpose of evaluation and research. However, it appeared that no specific norms of this test were available for an exclusive Negro population. Therefore, it seemed justifiable to develop a set of norms for this test based entirely on a narrowly defined Negro college population.

## Statement of the Problem

The problem of the study may be stated in the forms of specific questions as follows:

1. Are there any statistically significant mean differences on the Katson-Glaser Gritical Thinking Appraisal, the Dogmatism Scale, and the Test of Incependence of Judgment among Negro college students grouped by sex and academic status defined as bsing or not being in remedial programs?
2. What are the intercorrelations between scores on the subtests and the total test of the Hatson-Glaser Critical Thinking Appraisal, grade point averages, the Dogmatism Scale, the Test of Independence of Judgment, and the Scholastic Aptitude Test?
3. Are there any statistically significant differences in correlations among subgroups as olassified by sex and eacademic status?
4. What are the percentile ranks, reliabilities, and related data of the Hatson-Glaser Critical Thinking Appra1sal subtests and total test for freshmen, sophomores, males, females, and the combined groups?

## Purpose of the Study

- The purpose of the study was (1) to ascertain the adequacy of the HGCTA for use with Negro college students; (2) to establish Negro college norms and furnish normative data for the WGCTA; and (3) to ascertain factors which were presumed to be associated with performance of critical thinking.

## Assumptions and Limitations

The assumptions and limitations of the study can be stated as follows:

1. The study was limited to Negro college students of the freshman and sophomore classes in a southern Negro state college. The findings of the present investigation may not be generalized to any other population winch possess substantially different characteristics.
2. It was assumed that students who participated in this research were eager to cooperate and give accurate responses.
3. It was assumed that the instruments emplosisd did measure what they were supposed to measure. Also, the findings of the study were dependent to a large extent on the validity and reliability of these instruments.

## Organization of the Study

The report of the study was organized into five chapters in addition to sections containing reference and appendix sections. Chapter I includes a discussion of the need, the purpose, and the justification of the study. Chapter II is devoted to the review of related literature. The description of subjects, instruments, and methodology are narrated in Chapter III. Chapter IV presents and analyzes the data which are pertinent to the research problem. The summary of the investigation with conclusions and recommenations comprise the final chapter.

## CHAPTER II

## BEVIEW OF RELATED LITERATURE

Although critical thinking is generally recognized as one of the most desirable educational objectives, search of the literature revealed that research in the above area has been relatively meager. Such a gap might be ascribed to the lack of clear and comprehensive conceptions of what thinking involves on one hand, and the dearth of adequate instruments to evaluate its products on the other. Nevertheless, progress was made in the direction of clarifying the terms and analyzing the relationship between affective factors and performance of critical thinking. The following section mainly reports research germane to these two categories.

## Nature and Conceptions of Critical Thinking

As a global concept, critical thinking was sometimes considered connotatively to have similar meaning to "reflective thinking," scientific thinking," and particularly mogical thinking." Bdwards (19). for example, san no clearly apparent differences in meaning between the word "critical" and such descriptive terms as "rerlective;" elaborative,"
"soiontific," and "straight." Hyram(37) regarded thinking as oritical when it was essentially logical. Black (8) likewise conceived critical thinking and logical thinking as essentially the same. According to him, logic is the art and science of criticism of reasoning. A mastery of the rules and principles of logic is essential to cultivating systematic, persistent, and above all, oritical thinking.

Dewey's (15) work on reflective thinking provided a basis for evaluating the product of thinking. For Dewey, reflective thinking meant judgment suspended during further inquiry. To reflect was to hunt for additional evidence in order to corroborate or refute the first suggestion that occurred. To accept at once the suggestion that occurred would result in uncritical thinking. Thus reflective thinking, as Dewey emphasized, involved overconing the inertia that inclined one to accept suggestions at their face value, as well as willingness to endure a condition of mental unrest. (15)
"Inquiry" is another term which was found to be related to oritical thinking. In Logic: The Theory of Inguiry, Dewey (16) defined inquiry as:

- . . the controlied or directed transformation of an indeterminate situation into one that is so determinate in its constituent distinction and relation as to convert the elements of the original situation into a unified whole.

Bruner (il) emphasized that inquiry involved both analytic thought processes and intuitive grasp of the structures of a discipline. Massialas and Zevin (47) defined
inquiry as a mehavior which 18 characterized by a careful exploration of alternatives in seeking a solution to a problen." It embodies not only such cognitive tasks as construction of hypothesis, definition of terms, and validation of proposition, but also creative ideas and conjectual thinking.

Evaluative thinking is another term which approximates the concept of critical thinking. Buch (54) regarded evaluation as the kind of reasoning concerning judgment of the soundness or appropriateness of an idea or product. Critical thinking is evaluative in nature because it involves judging the suitability or goodness or effectiveness of an idea or representation. Guilford (30), in analyzing the nature of intelligence, identified evaluation as ma process of comparing a product of information with known information according to logical criteria, making a decision concerning criterion satisfaction." Similarly, Bloom (10) regarded evaluation as judging the value of materials and methods for given purposes by applying standards and criteria.

Critical thinking is closely related to evaluation in that it always involves some criteria and standards. Henderson (35) identified three R's in critical thinking, which he refered to as rating, rule, and reason. According to him, the critical thinker evaluates what he is thinking about by applying certain rules or criteria, which may be implicitly or explicitly stated. These guide his observations and thought. He rates the object of his thought, and justifies his rating
by reasons.
Russell (55) viewed critical thinking as the process of (1) examining both concrete and verbal materials in terms of related objective evidence, (2) comparing the object or statement with some norms or standards, and (3) concluding or acting upon the judgment then made. Russell also suggested that critical thinking depends upon the individual's background of information, his attitude of acceptance, or suspended judgment as well as his skills in applying standards.

Jelinek (38) viewed critical thinking as essentially a matter of interpreting facts, applying generalizations, and recognizing errors in logic. He refered to interpretation as evaluating ideas, making deduction, inferences, and generalizations and drawing conclusions on the basis of facts presented. Applying generalizations involves the ability to determine the conditions under which a concept will be satisfied and to recognize and devise reasons for the application of the principle. The skill of recognizing errors in logic includes the ability to detect propaganda; to recognize key words and distortion which would lead to false conclusions, and to avoid ridicule or appeals to prejudice in attempting to disprove logical statements.

Lack of clear conceptions of the specific behaviors that comprise the cognitive components of critical thinking led Eisner (20) to analyze this global concept into four
constituted parts. Eisner termed the first component of critical thought "questing," which is a conscious and deliberate pursuit of knowledge, exemplified by the student's independently initiated search for the problematic and his dispositinn towards wonder. The second component was that of mspeculation," which was viewed as the ability to generate models or theories to explicate phenomena. EEvaluation" was considered by Eisner as the third component of critical thinking. The criteria of evaluation involves three major dimensions. First, an idea or body of ideas in any field is evaluated for the logic of its propositions. The second type of criterion is concerned with evidence. The third type of criterion that is applied in the evaluation of propositions 18 of a qualitative variety, which refers to the ways in which language is organized, the types of words that are selected, and the emphasis given to certain phrases. The fourth component of critical thinking is that of "sonstructing.".. Constructing is the production of relationships or parallels between seemingly unrelated concepts. By means of the process of constructing, the individual is able to perceive elements as part of a larger whole and their relationships and interaction with each other.

Perhaps the most comprehensive attempt to refine the concept of critical thinking was made by Ennis (22). Stemming from the root notion that critical thinking is construed as the
correct assessment of statements. Bnnis identified twelve aspects of oritical thinking. He listed the twelve aspects of oritical thinking as:

1. Grasping the meaning of a statement.
2. Judging whether there is ambiguity in a line of reasoning.
3. Judging whether certain statements contradict each other.
4. Judging whether a conclusion follows necessarily.
5. Judging whether a statement is specific enough.
6. Judging whether a statement is actually the application of a certain principle.
7. Judging whether an observation statement is reliable.
8. Judging whether the inductive conclusion is warranted.
9. Judging whether the problem has been identified.
10. Judging whether something is an assumption.
11. Judging whether a definition 18 adequate.
12. Judging whether a statement made by an alleged authority is acceptable.

Ennis also proposed a three dimensional model of critical thinking which he referred to as logical, criterial, and pragnatic. The logical dimension involved judging alleged relationships between meanings of words and statements, while the criterial dimension included knowledge of the oriteria for judging statements, with the exception of the logical criteria which were covered in the first dimension. The pragmatic dimension covered the impression of the background purpose on the judgment as well as the decision as to whether the statement 18 good enough for the purpose.

## Critical Thinking and Belated Pactors

Research on critical thinking largely has been the study of the influence of emotional factors upon its performance.

The research by Frenkel-Brunswik (26), Adorno, et al. (1), Rokeach (53), and others have great implications for the study of the relationship between affective variables and critical thinking. These studies and other experimental evidence have repeatedly demonstrated that human cognitive processes are not free from the influence of the affective factors.

Among the early investigations of the relationship between emotional factors and the logicality of thoughts was Lefford's (44) study. The purpose of Lefford's study was to demonstrate the effect of verbal stereotypes on syllogistic reasoning and how attitudes and the factor of set might modify this behavior. The method consisted of presenting a questionnaire or 40 syllogistic problems to a group of college students. The syllogisms consituted two kinds of problems which were equated in terms of structure and length but differed in the content of the subject matter. Half of the syllogisms were of a socially controversial nature, which might arouse an emotional reaction, and the other half contained only materials of a neutral nature. The subjects were instructed first to judge the validity of the syllogisms and were then asked whether they would agrec or disegree with the conclusions. The first response was taken as an indication of their ability to solve syllogistic problems; the second as an indication of their opinions, belief, or attitude toward the subject matter. It was found that most subjects solved neutrally toned syllogisms more correctly than emotionally toned syllogisms. It
was also found that solving emotionally toned syllogisms first had a deleterious effect on the results of the subsequent solution of neutral syllogisms, while solving neutrally toned syllogisms first had a salutary effect on the subsequent solution of the affectively toned syllogisms.

Thistlethwaite (63) conducted a similar study in which non-syllogistic forms of inference were employed. The test materials consisted of seventy two arguments, of which thirty six were presumably of relatively neutral content, and thirty six presumably of emotional content. A total of 559 subjects were sampled from seven northern, western, and southern universities. Analysis of the covariance of errors on both neutral and emotional items indicated that the hypothesis that attitudes and beliefs were a determinant of reasoning should be rejected. When the groups from two sections were compared, it was found that the errors of distortion in reasoning were significantly higher for the southern subjects than for the northern subjects both on the ethnocentrism scale and the anti-Negro subscale.

The extent to which a person's attitude on a subject might interfere with his ability to think logically on that subject was investigated by Gorden (29). For the purpose of the study, Gorden constructed a syllogistic reasoning test with five possible conclusions for each syllogism. of the five conclusions, only one followed logically. Two conclusions were pro-Russian, and two were anti-Russian statements.

The results of the syllogistic test were then compared with the respondents' position on the ostensibly anonymous opinionnaire. It was found that the individual's attitude in a large minority of cases (1l out of 28) interfered with reasoning processes. of the eleven individuals who showed a total of forty responses, every individual was either all pro-or all anti-Russian.

An attempt was made by McNemar (48) to differentiate, within a college sample, individuals high from those low in reasoning ability with respect to (1) free and controlled word-association: (2) deduction and induction: and (3) experimentally induced set. A reasoning test, consisting of four subtests, was used as the criterion-measure. The upper 15 per cent and the lower 15 per cent of each sex distribution were selected to make up the high and low groups. The following were the conclusions of the study:

1. High and low groups did not differ in speed of unrestricted word flow, but did differ in speed of controiled association in favor of the high group.
2. Good reasoners were more accurate in both deductive and inductive processes and were faster in solving induction problems.
3. Good and poor reasoners differed significantly in the ability to solve problems in the volume-measuring series and overcome set. However, there was no significant difference in susceptibility to set.

The previous studies were concernod primarily with the influence of emotional factors upon logical thinking. Sholley and Davis (57) investigated to a further extent whether socially significant attitudes were related to errors in solving logical problems and whether these errors could be reduced or eliminated through instruction in logic. Two groups of college students served as subjects in the study, including twenty four who were not enrolled in a course in logic and thirty three who were enrolled in a symbolic logic class. A shortened form of the Thistlewaite test and a 20-item version of the California $F$ Scale were administered in the order mentioned. The distribution of the scores on the F Scale was divided at the median for each of the groups. Analysis of the data indicatea that the Iigh F Scale subjects in both groups made significantly more errors on the attitudinal items. It was also found that even though the number of errors were reduced as a result of training in logic, attitudes still significantly influenced scores. The authors, however, did not justify any conclusion without further investigation that low $F$ Scale subjects responded more according to logic than attitude.

Morgan (49) compared differences in logical reasoning among male applicants for government employment with respect to age and education. It was found that those who were in the twenty to twenty nine year-old group had higher scores in logical ressoning than the thirty to thirty-nine year-old
college graduates. The difference was statistically significant for those with bachelor's degrees but not for those with master's degrees.

Burton and Joel (14) reported the adult norms for the Watson-Glaser Tests of Critical Thinking. A total of 150 applicants for oivil service positions were tested. It was found that the norms for adults were higher then the WatsonGlaser norms for college seniors. The report also indicated that the subjects below the median age of 36.9 made higher mean scores on all four tests than those above the median age. All the differences were statistically significant. Comparison of subjects with two or more degrees with those who had no or one degree revealed no significant differences. However, the direction was in favor of those with two or more degrees.

A comparative study of certain value-patterns and critical thinking skills of graduate students was conausted by Bledsoe (9). The subjects consisted of twent.y-two males and twenty-four females who were enroiled in a graduate course entitled "hethods of Applied Research in Bducation" at the University of Georgia. The Allport-Vernon-Lindzey Study of Values and the Watson-Glaser Critical Thinking Appraisal were administered both before and after the intensive course in research methodology. Bledsole reported that while there were no significant differences in pre-course and endcourse mean scores in values, a significant difference in mean
scores on the Cultical Thinking Appraisel from pre-course to end-oourse was obtained. Comparison of mean difference in values and critical thinking for both sexes were found to be insignificant except for the Aesthetic Scale, on which women made a higher mean score.

Assuming that thinking is critical when essentially logical, Hyram (37) sought to test the hypothesis that ar. individual's growth in the ability to do logical thinking must depend upon his acquiring a working knowledge of the basic rules of logic. For experimental purposes, two groups of uppergrade children were equated in terms of (1) general intelligence, (2) mental age, (3) general reasoning ability, (4) general language proficiency, and (5) initia: reasoning ability. The children in the experimental group received instructional procedure which comprised both content material and teaching methods for 250 minutes per week. The content material was acquired through an analysis of tine understandings deemed basic to an adequate concept of logical thinking. The method employed was essentially the Socratic method and consisted of carefully phrased questions based on simple problems. The instruction given to the control group consisted of the regular classroom activities and standard subject matter content. A final test in reasoning was given to both groups and the difference in mean achievement was tested for signiricance. It was found that difference in achievement on the same test at the end of the experiment between the two
groups were highly significant in favor of the experimental Eroup.

Lehmann (43) used a longitudinal approach to investigate the ohanges occurring in college students ${ }^{\text {c }}$ critical thinkIng ability, attitudes and values from freshman to senior years. The Test of Critical Thinking along with other instruments was administered during orientation week to all native born American freshmen ( 1,436 males and 1,310 females) entering Michigan State University in the fall of 1958. Near the end of the senior fear the same instruments were again administered to these remaining students. It was reported that at the end of four jears of college, both males and females increased their critical thinking scores significantly. Students became more proficient in such tasks as the selection of pertinent information and the ability to formulate and select relevant hypotheses. It was also found that both males and females became more flexible, less rigid, and less authoritarian during their four years at college.

Kempt (39) compared those who were low with those who were high in dogmatism with respect to their ability in critical thinking. The sample was comprised of a total of 500 students from four colleges. The students were administered the Dogmatism Scale Form E, and the critical thinking problems. The 150 students with the highest scores and 150 with the lowest scores in dogmatism were selected for the comparison of results in critical thinking. Kempt found that the low group
was superior in ciritical thinking to the high group. He conooncluded that the less efficient performance of the highly dogmatic group was a result of their difficulty in tolerating ambiguities and their tendency toward an early "closure" before a full consideration of all factors involved. Moreover, the highly dogmatic students suffered from perceptual distortion of facts that resulted in decisions which did not encospass all elements of the problem. It was also pointed out by Kempt that the highly dogmatic students had a tendency to rejeot or ignore the significant parts of the whole problem in order to fit, into the performed value pattern.

The results of the above study led Kempt to the assumption that improvement in oritical thinking might also be influenced by the factor of dogmatism. In another study Kempt (40) thus hypothesized that students low in dogmatism would show greater improvement in critical thinking than those who were high. Por the purpose of the study, two groups of freshman students were equated in intelligence and in degree of open-and closemindedness. Both the experimental group and the control group were taught by the same instructor. The experimental group was divided into five subgroups, each of which consisted of four students who were high and four students who were low in dogmatism. All subgroups participated in ten one-hour meetings which were used in solving and discussing critical thinking problems. The controi group, however, was not given any special help in this regard. At the end of the study, it

21
was found that the experimental group did significantly better in oritical thinking than the control group. As far as improvement in oritical thinking was concerned, the "low" dogmatic students of the experimental group performed significantiy better at the 1 per cent level. The other groups, however, did not improve significantly.

## CHAPTER III

DESIGN AND PROCEDURE OF THE STUDY

This chapter discusses the procedure and methodology of the study. Space is given to the description of sampling procedure, the background characteristics of the subjects, and the instruments employed. The statistical treatment of data 18 also reported.

## Sampiting Procedure

The study was conducted at a predominantely Negro sollege located in a southern state. The college is a state supported, and teacher-education oriented institution. The sex ratio of the student body is about two to one in favor of the females. During the Spring Quarter of 1968, a total of 1,506 students were enrolled, of which 698 were frashmen and 330 were sophomores. Only Ireshman and sophomore students were included in this study. In order to keep the test adeinistration under manageable control, samples of 420 freshman and 220 sophomore students, which represented 60 per cent of the original population, were drawn randomly using a random digit table (27).

A letter signed by the Dean of Instruction was sent to each student requesting his cooperation in participating in the researoh project. The students were advised that the research was in the interest of improving the educational program and that their sincere cooperation was extremely important. The administration of the instruments was scheduled in three different settings. Follow-up letters were sent to those students who did not take the test as scheduled for the second and third time. A total of 355 freshmen and 151 sophomores completed all the instruments. This gave a grand total of 506 , which corresponded to about 82 per cent of the combined original sample.

## Description of the Subjects

Since the characteristios of the subjects determine to a large extent the results of the researsh, a detailed description of the subjects under study was considered necessary. at the time of testing, each subject was requested to fill out a separate questionnaire in order to secure background data with respect to family income, parental education, and fatheris occupation. The obtained data are reported in the following sections.

Total tamily income. On the average, subjects came from families of relatively deprived economic conditions, compared to an average college population. From the information furnished by the subjects regarding their total family incomes,
it was found that 21 per cent carned less than $\$ 2,400$ per year; 20 per cent earned between $\$ 2,400$ to $\$ 3.599 ; 30$ per cont fell in the range of $\$ 3,600$ to $\$ 5.999$; and 29 per cent reported an income of $\$ 6,000$ or more.

Parental education. A majority of the students in the sample, as illustrated from Table l, came from families with parents having only high school education or below. of partioular interest was the fact that the mothers tended to have received more education than the fathers. Twenty one per cent of the fathers terminated their education with grade sohool or less as compared to only 6 per cent of the mothers. On the other hand, twice as many of the mothers had received college degrees as had the fathers. The similar characteristics were also reported by Gurin and Katz (32).

TABLE 1
NUMBERS AND PERCENTAGES OF PARENTAL EDUCATION OF NEGRO COLLEGE STUDENTS

| Amount of Education | Father |  | Mother |  |
| :---: | :---: | :---: | :---: | :---: |
|  | N | \% | N | $\%$ |
| Grade school or less | 98 | 21 | 32 | 6 |
| Some high school | 218 | 47 | 255 | 51 |
| High school graduation | 85 | 19 | 99 | 20 |
| Some onllege | 37 | 8 | 57 | 12 |
| College degree or more | 24 | 5 | 54 | 11 |

Father's occupation. The occupational level of the fathers was in line with their attained educational level.

It was reported by the students that 81 per cent of the employed fathers had working-class ocoupations as compared to 19 per cent having middle-class or higher occupations.

From this background data, it appeared that, on the whole, this was a group that came from familiei of rather low socio-economic status. In fact, about 40 per cent of these students were from families whose annual incomes were below $\$ 3,600$, an economic condition that may be described as poverty (32). The relatively low educational attainnent of the parents might partially account for the low occupational status and hence, the deprived economic conditions.

## Description of the Instruments

Collection of data was based on two sources: the scores on the instruments and the student's academic record. The scores on the Scholastic Aptitude Test and each student's cumulative grade point average were obtained from the records office. The other instruments were administered on one single occasion. Descriptions of the major instruments are given below.

The Katson-Glaser Critical Thinking Appraisal. The
WGGTA is designed to provide a series of exercises which require the application of some of the important abilities involved in critical thinking. The problems and situations provided in the test are similar to those which a citizen in a democratic society might encounter in his daily life.

The test 18 available in two forms. Ym and 2m. Each form consists of five subtests which are designed to measure different but interdependent aspects of critical thinking. The HGGPA is a power test which requires no rigid time linit. Most persons, however, can complete the whole test in about fifty minutes. Watson and Glaser (64) described the five subtests as follows:

Test 1. Inference. (Twenty items.) Samples ability to discriminate among degree of truth or falsity of inferences drawn from given data.

Test 2. Recognition of Assumptions. (Sixteen items.) Samples ability to recognize unstated assumptions or presuppositions which are taken for granted in given statements or assertions.

Test 3. Deduction. (Twenty-five items.) Samples ability to reason deductively from given statements or premises; to recognize the relation of implication between propositions; to determine whether what may seem to be an implication or a necessary inference from given promises in indeed such.

Test 4. Interpretation. (Twenty-four items.) Samples ability to weigh evidence and to distinguish between (a) generalizations from given data that are not warranted beyond a reasonable doubt, and (b) generalizations which, although not absolutely certain or necessary, do seem to be warranted beyond a reasonable doabt.

Test 5. Evaluation of Argments. (Fifteen items.) Samples ability to distinguish between arguments which are strong and relevant and those which are weak or irrelevant i:o a particular question at issue.

The odd-even split-half reliability coefficients for the total test of Form Zm ranged from . 77 to .83 as reported in the test manual. The subtest split-half reliability coefficients for the Grade 10 normative groups are: Inference,
.55; Interpretation. .52; and Evaluation of Arguments, . 40. The intercorrelations between each of the subtests of Form 2a, and the total test as reported in the test manual ranged from . 56 to .76. The authors were not inclined to believe that the validity of a test could be generalized by a single correlation coefficient. They suggested that the aspect of validity should be considered in accordance with the situation in which the test is used (64).

The Dogmatism Scale. Developed by Rokeach (53), the soale was designed to measure individual differences in openness or closedness of bellef systems. The Scale may also be used for measuring general authoritarianism and general intolerance.

Form E of the Scale contained forty statements, which were answered by the degree of agreement or disagreement. For all statements, agreement was scored as closed, and disagreement as open. The highest possible score was 280 and the lowest possible score was forty. The total score on the Scale was the sum of scores obtained on all items.

The Scale was reported to have reliabilities ranging from . 68 to .93, which were claimed by the author to be quite satisfactory. The Scale was validated through a series of investigations. In one study, Rokeach (53) used the known method of validation. The graduate psychology students were asked to select friends who were considered to be open- and
closed-minded. The Scale was then adxinistered to these persons. It was found the Scale unambigu.5usly differentiated the high and low dogmatic groups in tne predicted direction.

Test of Independence of Judgment. This scale was developed by Barron (4) through an item analysis of 86 items. These items were carefully selected or written anew from an original pool of 200 items in an effort to test the particular hypotheses concerning personality differences between Independents and Yielders as identified in conformity experiments. The highest 27 per cent and the Iowesi 27 per cent of scorers on the Complexity Scale served as the criterion group because it was found that the Independents and Yielders were clearly different in their preference for complexity and simplicity. The questionnaire responses of the high group then were compared with the low group. Items which showed differences significant at the .05 level were included in the final 22item scale.

The pattern of responses to the Independence questionnaire items, as summarized by Barron, indicates that the preference for complexity is related to artistic interest, unconventionality, political radicalism, creativity, and a desire for change. Preference for simplicity, on the other hand, is associated with a disliking for modern art, friendliness toward tradition, categorical moral judgment, preference of symmetry to asymmetry, undeviating patriotism, and suppression of new
inventions which would temporarily cause unemployment. The reliability of this scale is not know.

Scholastic Aptitude Test. The College Entrance EramInation Board Scholastic Aptitude Test (SAT) is a well-known instrunent used by a large number of colleges and universities as a criterion of admission. The test is designed to measure general verbal and mathematical comprehension.

Form KSA 45 consists of five separately timed sections. Two scores are reported. The verbal score is based on antonyms, sentence completion, analogies, and reading comprehension items; the mathematical score is based on word problems and data sufficiency items.

Test-retest reilability coefficients are . 89 for the verbal scale and . 85 for the mathematical scale for time intervals up to ten months (13). Kuder-Richardson reliability coefficients for all forms range from . 88 to .91 for the verbal test and . 87 to . 91 for the mathematics test. The reliabilities of Form $\mathrm{KSA}_{45}$ are . 92 for verbal and . 93 for mathematics scores (13).

Some selected validity coefficients were reported to be modest for predicting scores of male liberal arts students as measured by freshman average grades. They ranged from . 16 to . 61 with a median of .35 for verbal scores, and from .15 to .53 with a median of .33 for mathematics scores. For female students, the range was found to be the same with median values of . 36 and . 26 for verbal and mathematics scores,
respectively (13).

## Statiatical Treatment of Data

The methods used in analyzing the data were deterained by the nature of the research problem. The following statistical techniques were employed in solving the problen.

1. Tests of significance involving differences in means, standard exror of the differences, and the oritical ratio of significance were used in determining whether there were any significant differences in mean scores between differont subgroups in test variables.
2. Pearson product-moment correlation coefficients were employed in determining the relationships between variables. Significance of the difference between two ris were computed in order to determine whether the differences in correlation coefficients between each subgroup were statistically significant.
3. Norm tables were established by computing percentile ranks of the raw scores obtained from the YGCTA. Means, standard deviation, split-half reliability coefficients correoted by Spearman-Brown formula, and the standard error of measurement were also computed.

## CHAPTER IV

## PRESENTATION AND ANALYSIS OF DATA

This chapter is divided into four major sections. The first two sections report the differences in mean values of scores on the HGCTA, the Dogmatism Scale, and the Test of Independence of Judgrent. Correlational analysis of the HGCTA and selected variables are presented in section three. Section four describes the development of norms for the WGCTA along with other relevant normative data.

## Comparisons of Mean Values on the WGCTA Test

The first step in analyzing the data was to determine whether the two samples dram separately came from two different populations with respect to performance on critical thinking. Table 2 presents the mean scores, standard deviations, and differences in means for the freshman and sophomore samples. As show in the table, there were no significant mean differences between these two samples on either the total scores or any of the subtest scores. However, the direction was in favor of the sophomores in all measures except in the Assumption subtest where both means were equal.

Since there were no significant mean differences between freshmen and sophomores, the original data were, therefore, pooled together for other comparisons. It was presumed from the outset that botin sex and academic status were important variables relative to the performance of oritical thinking. Academic status was defined as being or not leing in the remedial programs. More than 70 per cent of the students sampled were required to take either one or both remedial courses in Inglish or mathematics because of their deficiency in these two areas as judged by their previous records and relatively low scores received on some
table 2
MEAN SCORES, STANDARD DEVIATIONS, AND DIFFERENCES IN MEANS OF SCORES on the wgcta for freshian AND SOPHOMORE SAMPLES WITH SEX COMBINED

| WGCTA | Preshman |  | Sophomore Diff. |  |  | C.R. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathrm{M}_{1}$ | S.D.1 | $\mathrm{H}_{2}$ |  | $\mathrm{M}_{1}-\mathrm{H}_{2}$ |  |
| Inference | 6.1 | 2.6 | 6.3 | 2.7 | 0.2 | 0.77 |

| Interpretation | 12.4 | 2.8 | 12.7 | 2.8 | -0.3 | 1.11 |
| Arguments | 8.6 | 2.3 | 8:8 | 2.1 | -0.2 | 0.95 |
| Total Scores | 49.6 | 7.8 | 50.9 | 8.1 | -1.3 | 1.67 |

standardized tests. Those students who were required to take only one remedial course were eliminated in any further comparisons in view of their being in the middle-of-the-road
position as well as the either-or situation.
Comparisons of males with females in mean scores on the HGGYA with academic status being held constant yielded the results presented in Table 3. As shown in the table, the nonremedial males scores significantly higher than the nonremedial females in Deduction, Interpretation, and the total test. The nonremedial males had a mean total score of 57.9 as compared to 53.4 for the nonremedial females. The difference was significant beyond the one per cent level. For the two remedial groups, the males had significantly higher mean scores in Assumption and total critical thinking. However, the difference in total mean scores was barely significant at the 5 per cent level with respective values of 49.2 and 47.4 for the remedial males and remedial females. On the whole, it may be safely concluded that there are sex differences in favor of male students with respect to critical thinking abilities.

Differences in mean critical thinking scores between remedial and nonremedial students with sex being held constant are reported in Table 4. When the non-remedial groups were compared with the remedial groups, the differences in means were found to be highly significant in total critical thinking scores as well as in most of the subtests for both males and females. However, in the case of males, the difference between the remedial and nonremedial groups was not found to be statistically significant. The difference between the two female

*Significant at the 5\% level. **Significant at the 1\% level.

Comparisons of Mean Values on the Dogmatism
Scale and the Test of Independence of Judgment

Comparisons of mean differences on the Dogmatism Scale and the Test of Independence of Judgment are presented in Tables 5 through 8. Table 5 reports the differences in means between the nonremedial males and nonremedial females. It can be seen from the table that the females had a higher mean score in dogmatism than the males. The respective values for the males and females were 162.3 and 176.5 . The difference
wam significant at the 1 per cent lavel. This suggested that the females were nore dogmatic or olosedminded in outlook than the males. On the other hand, the males appeared to have higher mean score on independence of judgment. However, the difference was not statistically significant.

TABLE 5

## COHPARTSONS OF IRAN DIFFERENGES IN DOGMATISH AND INDEPENDENCS OF JUDGNIBNT BEYMEFN FONRENEDTAT MATES AND NONBBMEDTAL FBMATES

|  | ${ }_{1}$ | S.D.1 | $\mathrm{H}_{2}$ | $\mathrm{S.D.}_{2}$ |  |  |
| Degmatism | 162.3 | 26.8 | 176.5 | 21.6 | -14.2 | 2.94** |
| Ind. Judguent | 18.9 | 5.4 | 17.3 | 4.8 | 1.6 | 1.60 |

**Significant at the 1\% level.

Comparisons of the differences in means between the two remedial groups are presented in Table 6. It would appear that there were no sex differences in these two variables for those who were in the remedial programs. The obtained critical ratios of .38 and 1.29 were 80 small that the differences could be attributed to chance errors.

Table 7 presents the differences in mean between the nonremedial males and the renedial males. The mean scores of 162.3 for the nonremedial group and 182.3 for the remedial group were significantly different bejond the 1 per cent level
table 6
COMPARISOHS OF risan difrgebences in dogmatism ARD INDEPENDENGE OF JUDGIIENT BETVEEN herigdial males and bemedial fghales

| Variable | Hale |  | Pemale |  | Diff. | C.R. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | ${ }_{1}$ | S.D.1 | $\mathrm{H}_{2}$ | 3.D. 2 |  |  |
| Dogmatism | 182.3 | 23.6 | 183.5 | 20.8 | -1.20 | . 38 |
| Ind. Judgment | 17.0 | 4.5 | 16.2 | 4.5 | 0.80 | 1.29 |

in the case of dogmatism. This indicates that the nonremedial males were more open than the remedial males in their bellef system. Comparison of the mean scores on independence or judgment rendered a difference of 1.9 score points, which was significant at the 5 per cent level in favor of the nonremedial group. The nonremedial males obtained a mean score of 18.9 as compared to 17.0 for the remedial males.

TABLE 7
COMPARISONS OF MEAN DIFFEBENGES IN DOGMATISM AND INDEPENDENCE OF JUDGMENT BETHEEN NONREMIEDIAL MALES AND BEHEDIAL MALES

| Variable | Nonremedial |  | Bemedial |  | Diff. | C.R. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | ${ }_{1}$ | 3.D.1 | ${ }_{2}$ | S.D. ${ }_{2}$ |  |  |
| Dogmatism | 162.3 | 26.8 | 182.3 | 23.6 | -20.0 | 4.08** |
| Ind. Judgment | 18.9 | 5.4 | 17.0 | 4.5 | 1.9 | 1.96* |

[^1]Table 8 presents the mean difference between the two fomale groups. As in the case of the males, the nonrenedial females also had a smaller mean score (176.5) than the remedial females (182.3) in dogmatism. The difference was significant at the 1 per cent level. The mean difference between the two groups in independence of judgment, however, was not statistically significant.

From the above comparisons, it may be concluded that the nonremedial students, whatever their sex, tended to be less dogatic and more independent in their judgment than their counterparts. In general, males appeared to be more open in their beliof systen than females. However, this was true only for those who were not in the remedial programs. For those who were required to take remedial courses, it appeared that the males were as dogmatic as the females.

## Correlational Ansiveis of the Subtest and Total Soores on the RGYA and Selected Variables

The Pearson product-moment coefficient of correlation was emplojed as the statistical technique to determine the relationship among oritical thinking scores and other selected variables. It has generally been recognized that the coefficient of correlation is very much dependent on the range of talents within the group. In order to obtain a valid measure of relationships, Woodworth (67) insisted that the coefficient must be freed of the extraneous influences which affect the relationship between the variables concerned. Guilford(31) likewise suggested that it would be bust to compute correlations within subsamples separately if it was doubtful whether subsamples arose by random sampling from the same population. For this reason, the correlation coefficients were computed separately for the four groups which were isolated by sex and academic status. It has already been shown in the previous sections that these groups differed one way or another in critical thinking as well as in belief systems.

Tables 9 through 12 present the intercorrelations anong critical thinking scores, grade point averages, scores on the Scholastic Aptitude Test, dogmatism, and independence of judgment for each of the four groups. The differences between correlations were determined by using $Z$ transformations as suggested by Guilford (31). The required levels
of significance are the same as those applied to the differences between means.

Table 13 reports the $\mathbf{Z}$ transformations of the differences in correlations between the nonremedial males and nonremedial females. It can be seen from the table that the correlations which differed significantly include AssumptionSAT(V), Assumption-SAT(M), Assumption-Deduction, and Interpre-tation-total oritical thinking scores with respective values of -.25. -.23. -.07. and . 74 for the males and .23. .16. .34, and .48 for the females. The correlation between grade point average and $\operatorname{SAT}(\mu)$ failed to reach the required level of significance with values of . 60 for the females and .30 for the males.

Comparisons of the differences in correlations between the remedial males and remedial females are presented in Table 14. Significant differences were found in the relationship between GPA and SAT(V) with coefficients of -. 16 and .23 for males and females respectively. The correlation coefficient of -. 08 obtained for the remedial males also differed significantly from the value of .29 obtained for the remedial females in the correlations between GPA and Inference. In both cases, the differences were significant beyond the 1 per cent level.

Table 15 presents the Z values of the differences between the correlations obtained for the nonremedial males and the remedial males. Differences significant beyond the 1 per cent level were the correlations of GPA-SAT( $V$ ), and
.67 for the nonremedial males and -.16 and .20 for the remedial males. Other significant differences in correlations between these two groups included SAT(V)-Assumption. Inference-Assumption, and Interpretation-Argument. For the nonremedial males, the respective coefficients were $-.25 . .39$. and .47; for the remedial males, they were .14, .02, and .09.

Table 16 presents the $Z$ values of the differences in correlations between the nonremedial females and the remedial females. The correlated veriables which were found significantly different in four comparisons included GPA-SAT(H), SAT(V)-SAT(M), Dogmatism-Independence of Judgment, and Assump-tion-Deduction. The correlation between grade point average and SAT(H) was moderately high for the nonremedial females with a coefficient of . 60 as compared to only . 10 for the remedial females. The correlations between the two subtests of SAT were also significantly different with values of .56 for the nonremedial females and . 24 for the remedial females. The nonremedial females had coefficients of -.23 and .34 in the correlations between dogmatism and independence of judgment, as well as Assumption and Deduction. In contrast, the remedial females received values of .07 and .05 in the two correlations respectively.

## Norms of the HGCFA and Other Romative Data

One of the major purposes of the present investigation was to establish a set of norms for the MGTA based on samples from a Negro college. It has been generally recognized that norms are restricted to the characteristics of the particular population from which they were derived. Therefore, in no sense can norms be considered as absolute and universal. To compare test scores derived from two different populations without making reference to their respective characteristics may be of little value and even misleading. Womer expressed this concern when he clearly pointed out that:

> pupils (atypical in terms of educational opportunities) may not be judged niairlyn by a test which assumes equal educational backgrounds. Some may have had very rich opportunities to learn, other very meager ones. The differences among their scores-e or some part of the differencesmomay, then, be chargeabie to differences in opportunity rather than in ability. ( 66 ).

As a group, the subjects in this study came from families which were deprived economically, socially, as well as educationally. It was expected that these background characteristics might be partially reflected in scores they madé on the test.

The norms for the WGCPA subtests and total test were presented in percentile rank form. The percentage of cases in a distribution that lay below any given score was called the
percentile rank of that score. The method of computing percentile rank, as proposed by Wert, Neidt, and Ashmann (65), was to divide the appropriate entry in the cumulative frequency colum by the total number of cases and then multiply by 100. The result is always rounded upward to the nearest whole number.

Tables 17 through 22 are percentile ranks of scores on the Critical Thinking Appraisal subtests and total test. Percentile ranks were computed for freshman and sophomore students E=parately as well as combined. Because of the substantial sex differences found in critical thinking scores, percentile ranks were also computed for the two sexes regardless of their academic classification.

A raw score is converted to a percentile rank by locating the raw score in the first column of the table, then reading the percentile rank to the right. For example, a raw score of 50 corresponds to a percentile rank of 57 for the freshman class and 49 for the sophomore class. This means that a certain student who obtained a score of 50 , performed better or as good as 57 per cent of the total freshman students and 49 per cent of the total sophomore students in the norm groups.

It appeared that in general the students in the nor-
 It can be seen from Table 18 that 94 per cent of the combined group had scores of 10 and below out of a possible score of
20. This may be explained by the fact that the Inference subtest calls for greater ability in reading comprehension and that the subjects were relatively handicapped in their use of the English language. In contrast. students appeared to have done better in other subtests which were less dependent on reading ability. This suggested that deficiency in English, as evidenced by the fact that a great majority of students were in remedial English programs, might have been an important factor contributing to the scores derived from the Critical Thinking Appraisal.

The reliability data of the critical thinking scores are reported in Tables 23 through 27 for the normative groups. The means, ranges of scores, standard deviations, and standard errors of measurement are also included in these tables. All reliabilities are expressed in terms of split-half reliability coefficients, which were computed by correlating the total correct scores on the odd items with the even items. The obtained coefficients were then corrected by Spearman-Brown formula to yield the reliability coefficients.

The reliability coefficients obtained for the separate subtests were rather low with a range from . 11 on the Argument test to .51 on the Inference test found in the sophomore group. The reliability coefficients of the total test ranged from . 55 for the females to . 73 for the males. In most instances, the reliability coefficients were found to be lower than those reported in the manual. This could be expected since reliability
is a function of group variability. The fact that the ranges of ability represented in the groups were relatively narrow might partially account for the moderately low values of the obtained reliability coefficients.

The standard errors of measurements for the separate subtests as well as the total test are reported in the last column of the tables. The standard error of measurement is defined as an estimate of the root-mean-square departure of a series of observed scores from their corresponding true scores (21). The formula used in computing this statistic, as suggested by Kerlinger (41), is as follows:

$$
S E_{\text {meas }}=S D_{t} \sqrt{I-I_{t t}}
$$

Where: $\mathrm{SE}_{\text {meas }}=$ standard error of measurement $\mathrm{SD}_{\mathrm{t}}=$ standard deviation

$$
r_{t t}=\text { reliability coefficient }
$$

The standard error of measurement is of particular value when it is used to indicate the spread of errors of measurement around a true score. The standard error of measurement is usually relatively independent of exact spread of scores, and, therefore, its value can be applied directly to new groups which may differ considerably in variability from the group on which the standard error of measurement was originally determined (46).

The values of the obtained standard error of measure-
ment were fairly constant from group to group. The values for the total test ranged from 4.59 to 4.86 , which were slightly larger than those reported in the manual. The smaller the standard error of measurement, the more accurate the scores would be in the sense that they more closely distribute themselves around the examinee's true score. The standard error of measurement of 4.74, as reported in Table 25. would mean that for any freshman students the chances are that 68.26 percent of the time his true score would lie somewhere between 4.74 score points above or below his obtained score. Likewise, about 95 per cent of the time, his true score would fall between two standard errors of measurement, or 9.48 score points above or beloy his obtained score.

SUMIMARY, CONCLUSIONS, AND BECOMAENDATIONS

The problem of the study was: (1) to determine whether there were significant differences in critical thinking, dogmatism, and independence of judgment among Negro college students when classified by academic status and sex; (2) to determine whether there were significant differences among the student subgroups in the intercorrelations between critical thinking abilities, dogmatism, independence of judgment, scholastic aptitude, and grade point average; and (3) to establish norms for the Hatson-Glaser Gritical Thinking Appraisal based on exclusively Negro college samples.

A total of 506 students in both freshman and sophomore classes were chosen randomly as subjects for the study. All subjects were Negroes who were enrolled in a predominately Negro state college located in a southern state. As a group, the subjects came from families which were relatively deprived economically, socially, and educationally. A great majority of the students were placed in the remedial programs because of their deficiencies in English and mathematics. The instruments administered to the subjects included
a personal data sheet, the Watson-Glaser Critical Thinking Appraisal, the Dopmatism Bcale, and the Test of Independence of Judgent. The verbal and mathematics scores of the Scholastic Aptitude Test as well as grade point averages were obtained from the college's records office. The data were computed and analyzed through the help of the computer system at the University of Oklahoma.

Major findings of the study may be sumarized as

## follows:

1. There were no statistically significant differences in critical thinking scores (subtest as well as the total raw scores) between freshman and sophomore students.
2. With academic status being held constant, the nonremedial males were found to have significantly higher mean scores in Deduction, Interpretation, and total critical thinking scores than the nonremedial females; whereas, the remedial males had significantly higher mean scores in Assumption and total oritical thinking than the remedial females. 3. With sex held constant, the nonremedial males were found to have significantly higher mean scores in Inference, Deduction, Interpretation, Argument, and total oritical thinking than the remedial males; whereas, the nonremedial females had significantly higher mean scores in Inference, Assumption, Interpretation, Argument, and total critical thinking than the remedial females.
3. The nonremedial females had significantly higher
mean scores in dogmatism than the nonremedial males.
4. There mere no significant mean differences in dcgatism and independence of judgment between the remedial males and remedial females.
5. Nonremedial males had a significantly higher mean scoresin independence of judgment, while the remedial males had significantly higher mean scores in dogmatism.
6. Remedial females had significantly higher mean scores in dogmatism than nonremedial females. No significani difference was found between the two groups in independence of judgment.
7. Differences in correlations between the nonremedial males and nonremedial females were found to be significant in Assumption-SAT(V), Assumption-SAT(M), and Assumption-Deduction in favor of the females. The males had significantly higher coefficients in the reletionship between Interpretation and total oritical thinking.
8. Significant differences in correlations between the remedial males and remedial females were found in GPA-SAT $(\nabla)$, and GPA-Inforence in favir of the females.
9. Significant differences in correlations between the nonremedial males and remedial males were found in GPASAT(V), SAT(V)-SAT(H), SAT(V)-Assumption, Inference-Assumption, and Interpretation-Argment. With the exception of the correlation between SAT(V) and Assumption, all other differences found signifisant were in favor of the nonremedial group.
10. Significant differences in correlations between nonremedial females and remedial females were found in GPASAT( $M$ ), SAT(V)-SAT( $M$ ), Dogmatism-Independence of Judgment, and Assumption-Deduction. All differences were in favor of the nonremedial group.
11. In general, students in the sample did least well in the Inference subtest which called:for greater ability in reading comprehension.
12. Split-half reliability coefficients of the WatsonGlaser Critical Thinking Appraisal ranged from . 55 for the females to .73 for the males. The reliability coefficients were relatively low as compared to those reported in the manual.

## Recommendations

In light of the findings, the following recommendations are made:

1. A subtest scores on the WGCTA may not be useful in evaluating individual attainment in any single sub-skill of critical thinking due to the moderately low subtest reliabilities. It is recommended that the total critical thinking score be utilized whenever the evaluation of individual performance is desired.
2. On the average, the students in the study were relatively hampered in making inference. Therefore, the development of ability to make inference is the type of

71
critical thinking training that is most needed by the group.
3. The rather low and even negative correlations between grade point average and SAT scores found for the two remedial groups suggests that there is a need for the institution to reconsider the value of the Scholastio Aptitude Test for the purpose of predicting academic achievement insofar as the remedial students are concerned.
4. It is recommended that further studies be carried out to establish norms for Negro students on other important standardized tests. It 18 further recommended that Negro educators develop and standardize some aptitude tests which are appropriate for this segment of the population.

4. Date of Birth:

Month
Day
Year
5. Classification: Freshman $\qquad$ Sophomore $\qquad$
Other (specify) $\qquad$
6. What is your religious afîiliation?
Protestant $\qquad$ (Specify denomination)
$\qquad$ Catholic $\qquad$ Other (specify) $\qquad$ None
7. Are(were) you required to take remedial English? Yes No $\qquad$
8. Are(were) you required to take remedial mathematics? Yes $\qquad$ No $\qquad$
9. What is your father's occupation? (Specify) $\qquad$
10. What was the last grade your father completed in that school or college? (Circle one)

11. What was the last grade your mother completed in that school or college? (Circle one)

12. What is the total amount of your family yeariy income? (Approximately)

APPENDIX B
THE DOGMATISM SCALE

## APPENDIX B

## THE DOGMATISM SGALE

The following is a study of what the general public thinks and feels about a number of important social and personal questions. The best answer to each statement below 18 your personal opinion. We have tried to cover many different and opposing points of view; you may find yourself agreeing strongly with some of the statements, disagreeing just as strongly with others; whether you agree or disagree with any statement, Jou can be sure that many people feel the same as you do.

Mark each statement in the left margin according to how much you agree or disagree with it. Please makr every one. Write $+1,+2,+3$, or $-1,-2,-3$, depending on how you feel in each case.
+1: I AGREE A LITTLE -1: I DISAGREE A LITTLE
+2: I AGREE ON THE WHOLIE -2: I DISAGREE ON THE WHOLE
+3: I AGREE VERY MUCH -3: I DISAGREE VERY MUCH

1. The United States and Russia have just about nothin in common.
2. The highest form of government is a democracy and the highest form of democracy is a government run by those who are most intelligent.
3. Even though freedom of speech for all groups is a worthwhile goal, it is unfortunately necessary to restrict the freedom of certain political groups.
4. It is only natural that a person would have a much better acquaintance with ideas he believes in than the ideas he opposes.
$\qquad$ 5. Man on his own is a helpless and miserable creature.
5. Fundamentally, the world we live in is a pretty lonesome place.
_ 7. Most people just don't give a "damn" for others.
—— 8. I'd like it if I could find someone who would tell me how to solve my personal problems.
6. It is only natural for a person to be rather fearful of the future.
$\qquad$ 10. There is so much to be done and so little time to do it in.
___ 11. Once I get would up in a heated discussion $I$ just can't stop.

$\qquad$ 31. My blood boils whenever a person stubbornly refuses to admit he's wrong.
7. A person who thinks primarily of his own happiness is beneath contempt.
8. Most of the ideas which get printed nowadays aren't worth the paper they are printed on.
9. In this oomplicated world of ours the only way we can know what's going on 18 to rely on leaders or experts who can be trusted.
10. It is often desirable to reserve judgment about what's going on until one has a chance to hear the opinions of those one respects.
11. In the long run the best way to live is to pick friends and associates whose tastes and beliefs are the same as one's own.
12. The present is all too often full of unhappiness. It is only the future that counts.
13. If a man is to accomplish his mission in life, it is sometimes necessary to gamble "all or nothing at all."
14. Unfortunately, a good many people with whom I have discussed important social and moral problems don't really understand what's going on.
15. Most people just don't know what's good for them.

## APPENDIX C

## TEST OF INDEPENDENCE OF JUDGYENT

## APPENDIX $C$

## TEST OF TNDEPENDENCE OF JUDGYENTT

Please circle either True(T) or False(F) for eachof the following statements.

1. I would enjoy the experience of living and ..... T ..... $F$
working in a foreign country.
2. I prefer team games to games in which one ..... $T$ ..... F
individual competes against another
3. The unfinished and the imperfect often have ..... $\boldsymbol{T} \quad \mathbf{F}$ greater appeal for me than the completed andthe polished.
4. Disobedience to the government is never ..... $T \quad \mathbf{F}$5. I could cut my morrings . . . quit my home,$\boldsymbol{T} \quad \mathbf{F}$my parents and my friends . . . withoutsuffering great regrets.
5. Things seem simpler as you learn more about ..... $T$them.
6. When a person has a problem or worry, it is ..... T $\mathbf{F}$ best for him not to think about it, but tokeep busy with more cheerful things.
7. Perfect balance is the essence of all good ..... $T \quad \mathbf{F}$composition.
8. Politically, I am probably something of a ..... $T$
radical.
9. Kindness and generosity are the most important qualities for a wife to have.$T$F
10. An invention which takes jobs away from people ..... $T$ should be suppressed until new work can be found for them.
11. I think I take primarily an esthetic view of ..... T ..... F
experience.
12. It 18 a pretty callous person who does not feel ..... $T$ ..... F
love and gratutude toward his parents.
13. When someone talks against certain groups of ..... $T$ ..... F
nationalities, I always speak up against such talk, even though it makes me unpopular.
14. It is the duty of a citizen to support his ..... $T$ ..... F
country, right or wrong.
15. Barring emergencies, I have a pretty good idea $T$ ..... Fwhat Iill be doing for the next ten years.
16. Hany of my friends would probably be considered ..... $\mathbf{T}$ ..... $\mathbf{F}$ unconventional by other people.
17. I don't like modern art. ..... F
18. Some of my friends think that my ideas are ..... $T$ ..... Fimpractical, if not a bit wild.
19. I much prefer symmetry to asymmetry.
20. Stralghtforward reasoning appeals to me more than metaphors and the search for analogies.
21. I enjoy discarding the old and aocepting the T $\mathbf{F}$ new.

## APPENDIX E

FREQUENCY DISTRIBUTION OF SCORES ON THE DOGMATISM SCALE FORM E

## APPENDIX E

PRERUENCY DISTRIBUTION OF SCOBES ON TUE DOGMATISH SCALE FORM E

| Class Interval | Erequency |  |
| :---: | :---: | :---: |
|  | Male | Female |
| 239-247 | 1 | 1 |
| 230-238 | 3 | 3 |
| 221-229 | 2 | 7 |
| 212-220 | 10 | 17 |
| 193-211 | 30 | 76 |
| 184-192 | 25 | 51 |
| 175-183 | 20 | 61 |
| 166-174 | 26 | 38 |
| 157-165 | 21 | 32 |
| 148-156 | 14 | 26 |
| 139-147 | 7 | 9 |
| 130-138 | 6 | 8 |
| 121-129 | 4 | 4 |
| 112-120 | 2 | 1 |
| 103-111 | 1 | 0 |

## APPENDIX F <br> FREQUENCY DISTRIBUTION OF SCORES ON THE <br> TEST OF INDEPENDENCE OF JUDGYENT

## APPENDIX $\mathbf{F}$

FREQUENCY DISTBIBUTION OF SCORES ON THE TESTT OF INDEPENDENCE OF JUDGYENT

| Class Interval | Frequencr |  |
| :---: | :---: | :---: |
| $31+$ | 1 | Female |
| $29-30$ | 1 | 1 |
| $27-28$ | 3 | 2 |
| $25-26$ | 6 | 8 |
| $23-24$ | 14 | 20 |
| $21-22$ | 18 | 30 |
| $19-20$ | 23 | 35 |
| $17-18$ | 32 | 67 |
| $15-16$ | 22 | 55 |
| $13-14$ | 24 | 43 |
| $11-12$ | 13 | 38 |
| $9-10$ | 11 | 18 |
| $7-8$ | 4 | 2 |
| $5-6$ |  | 3 |
| $3-4$ |  | 2 |

## APPENDIX G <br> FREQUENCY DISTRIBUTION OF GRADE POINT AVERAGES

## APPENDIX G <br> FREQUENCY DISTRIBUTION OF GRADE POINT AVEBAGES

| Class Interval | Frequency |  |
| :---: | :---: | :---: |
|  | Male | Female |
| 3.70-3.89 |  | 2 |
| 3.50-3.69 | 2 | 4 |
| 3.30-3.49 | 3 | 2 |
| 3.10-3.29 | 0 | 8 |
| 2.90-3.09 | 4 | 19 |
| 2.70-2.89 | 8 | 16 |
| 2.50-2.69 | 4 | 31 |
| 2.30-2.49 | 22 | 37 |
| 2.10-2.29 | 20 | 50 |
| 1.90-2.09 | 43 | 55 |
| 1.70-1.89 | 17 | 38 |
| 1.50-1.69 | 18 | 25 |
| 1.30-1.49 | 12 | 24 |
| 1.10-1.29 | 8 | 9 |
| 0.90-1.09 | 4 | 9 |
| 0.70-0.89 | 4 | 1 |
| 0.50-0.69 | 1 | 1 |
| 0.30-0.49 | 2 | 1 |
| 0.10-0.29 |  | 2 |

[^0]:    AMale: Renedial $\mathrm{N}=73$; Nonremedial Nm45 Penale: Remedial Na188; Nonremedial K=68 significant at the 5\% level. *isignificant at the 1\% level.

[^1]:    *Significant at the $5 \%$ level.
    **Significant at the 1\% level.

[^2]:    *Significant at the 5\% level.

[^3]:    ** Sigaificant at the 1\% level.
