## PREFACE

This program was written to mechanize the solution of a practical problem in the field of applied statistics. It demonstrates the flexibility and capacity of a medium-sized computer. Program storage space was held to a minimum by maintaining in memory only that portion of the program which was being utilized at that stage of data processing.

Indebtedness is acknowledged to Dr. Robert D. Morrison, who served as chairman of my advisory committee, for suggesting this problem and for his careful guidance in the development of this program; to Mr. Paul Eugene Pulley, Jr., for his numerous suggestions and tireless efforts in assisting in the programming of this problem; to Dr. David L. Weeks for suggestions concerning matrix notation; to Dr. O. H. Hamilton for serving on my advisory committee; to Dr. L. Wayne Johnson for giving me the opportunity to work at the Oklahoma State University Computing Center; and to my wife, Flodema, for her unselfish sacrifices and contribution to this program.

## CHAPTER I

### INTRODUCTION

In many cases the least squares analysis of data with unequal subclass numbers is obtained by solving the normal equations. This set of normal equations in most cases is a less than full rank system. In order to get a unique solution, restrictions are made on the set so that the new system will be of full rank.

One way to arrive at a unique solution is to obtain the normal equations, make a transformation on the set of equations, then invert the coefficient matrix. This thesis describes how to carry out this procedure on the IBM 650 Electronic Digital Computing Machine equipped with floating point device, index register and sixty words of immediate access core storage for models having no more than two way interactions and at least one observation in each cell.

Due to the size of memory storage and the fact that matrix manipulations require a large storage, the program consists of three basic phases:

- (1) Phase I is the program for building the normal equations from the raw data.
- (2) Phase II is the program for making the transformation on the equations so that the new system is reduced to full rank.

(3) Phase III is the program for inverting the matrix, obtaining estimates of the parameters and obtaining reductions in the sums of squares for each set of attributes after adjusting for all others.

The Programs are given in Appendix A, Tables 1, 2 and 3, respectively.

Due to storage limitation card handling could not be avoided. The overall procedure has been arranged to accomplish the following objectives:

- (1) To operate the Computing Machine with ease.
- (2) To require a minimum amount of card handling.
- (3) To give optional read-in and punch-out features.
- (4) To be able to start at any one of four particular levels of processing.
- (5) To keep a maximum size of matrix.
- (6) To exhibit the results so that they can easily be identified.
- (7) To use a standard (80-80) board in the 533 Machine, i.e., a panel wired such that the data can be in the format of eight ten digit words as indicated on an IBM 5280 General Purpose Eight Field Card.

## CHAPTER II

### THE PROGRAM: PHASES I AND II

#### Procedures for Processing

Phase I consists of a program from the library of the Oklahoma State University Computing Center which is used to obtain sums of squares and crossproducts. Operation procedures for this program have already been written and are on file in the Oklahoma State University Computing Center. The write-up for Phase I is in Appendix B. Phase I is the first level of processing.

The basic function of Phase II is to make the transformation on the normal equations. Let  $X'XB = X'Y$  be the normal equations where  $X'X$  and  $X'Y$  are the sums of squares and crossproducts produced by Phase I. The matrix  $X'X$  will be assumed to be a  $(p \times p)$  matrix of rank  $n$ ,  $n \leq p$ ;  $X'Y$  is a  $(p \times r)$  matrix. If  $T_L = T | \emptyset$  and  $T_R = \frac{T'}{\emptyset} | I$  where  $T_R$  is  $(p + r) \times (n + r)$ ,  $T_L$  is  $(n) \times (p + r)$ ,  $T'$  is  $(p \times n)$ ,  $\emptyset$  is a matrix of zeros,  $I$  is an  $(r \times r)$  identity matrix and  $T$  is constructed so that  $T(X'X)T' = R$ , where  $R$  is  $(n \times n)$  of rank  $n$ . If  $A = \frac{X'X}{Y'X} | \frac{X'Y}{Y'Y}$ ,  $T_L AT_R = (T | \emptyset) \left( \frac{X'X}{Y'X} | \frac{X'Y}{Y'Y} \right) \left( \frac{T'}{\emptyset} | I \right) = T X'XT' | T X'Y = R | G$  where  $G = TX'Y$ . This phase of the program calculates  $R | G$ .

The elements of the transformation matrix are determined

by the mathematical model and the restrictions made on the parameters. This phase is applicable for any model to which the T matrix can be constructed. Essentially the T matrix is a set of restrictions on the set of equations  $X'XB = X'Y$  so that a particular solution can be found for the normal equations.

In order to explain the details of the operating procedures, a set of data  $X | Y$  from a pamphlet by Harvey<sup>1</sup> will be used. The data in punch-card format with proper header card and proper trailer card is given in Appendix A, Table 4. The layout of the header card and trailer card is given in Appendix A, Tables 5 and 6 respectively. The format for  $X | Y$  is given in Appendix A, Table 7. The output of Phase I with header card is in Appendix A, Table 8.

Three right hand members have been used in order to show the flexibility of the program. The first of these is the actual data in Harvey's<sup>2</sup> pamphlet; the other two are fictitious data.

The mathematical model underlying the analysis to be made with these data is

$$y_{ijkm} = u + g_i + s_{ij} + a_k + (ga)_{ik} + bA_{ijkm} + dW_{ijkm} + e_{ijkm}$$

$$\begin{array}{ll} i = 1, 2, 3 & k = 1, 2, 3 \\ j = 1, 2, 3, \dots, & m = 1, 2, \dots, \end{array}$$

<sup>1</sup>Walter R. Harvey, Least Squares Analysis of Data with Unequal Subclass Numbers, Agricultural Research Service Pub. No. ARS-20-8 (Washington, 1960), P. 103.

<sup>2</sup>Ibid.

where:  $y_{ijkm}$  = the average daily gain for the  $m^{th}$  steer in the  $k^{th}$  age of dam class by the  $j^{th}$  sire of the  $i^{th}$  line,

$u$  = the theoretical population mean with equal subclass frequencies when weaning age and initial weight both are equal to the absurd value of zero. The population mean with equal frequencies when the weaning age and initial weight both are equal to the average is

$$= u + b\bar{A} + d\bar{W},$$

$g_i$  = effect of the  $i^{th}$  breeding group or line,

$s_{ij}$  = effect of the  $j^{th}$  sire in the  $i^{th}$  line,

$a_k$  = effect of the  $k^{th}$  age of dam class,

$(ga)_{ik}$  = interaction effect for line and age of dam,

$b$  = partial regression of average daily gain (ADG) on age at weaning. Since all steers were placed on test at the same time this regression coefficient will measure the effect of time of birth on ADG in the feed lot,

$A_{ijkm}$  = age at weaning for a given steer,

$d$  = partial regression of ADG on initial weight,

$W_{ijkm}$  = initial weight for a given steer,

$e_{ijkm}$  = random error.

Since the example output of the Phase I program is a  $(p + r) \times (p + r)$  matrix, the  $T_R$  matrix must be a  $(p + r) \times (n + r)$  in which  $n$  is the rank of the reduced matrix  $R$ ,  $r$  is the number of right hand members in the system and  $p$  is the dimension of the  $X'X$  matrix. For this sample case  $n$  is 17,  $r$  is 3 and  $p$  is 27, making  $T_R$  a  $30 \times 20$  matrix.

A Program for Least Squares Analysis of Data with Unequal Subclass Numbers assumes the  $T_R$  matrix is already built.

The  $T_R$  matrix may be stored in the machine or it may be read in by this program. It may be in fixed-point or in either of two floating-point modes. The card format is the same as the Phase I output. The two floating-point formats are (1) 50x.xxxxxxx and (2) x.xxxxxxx51; the fixed-point format is 0000000001.

If the  $T_R$  matrix is already stored in the machine it must be in row sort with the first element in location 0000 and the elements must be in the floating-point mode x.xxxxxxx51.

If the  $T_R$  matrix is to be read into the machine by this program it must be preceded by a proper header card. The  $T_R$  matrix header card format is given in Appendix A, Table 9.

The  $T_R$  matrix for this example was constructed in the fixed-point mode and is given with the header card in Appendix A, Table 10.

The following is a step by step description of the technique used in constructing the  $T_R$  matrix for this example from a 30 x 30 identity matrix:

- (1) Subtract the matrix row associated with  $(g_3)$ , the last  $g$  row, from all the other  $g$  rows, i.e., from rows  $g_1$  and  $g_2$ . Delete the  $g_3$  row of the matrix.
- (2) Subtract the row associated with  $s_{lk}$  from each row,  $s_{l1}, s_{l2} \dots s_{l, k-1}$  where  $k$  is the last group in the  $s_{lj}$  group. Delete the  $s_{lk}$  row of the matrix from this group.
- (3) Repeat step 2 above for the remaining rows.

- (4) In the same manner as step 1 above, subtract the matrix row associated with the last a row, ( $a_3$ ), from all the other a rows, i.e.,  $a_1$  and  $a_2$ . Delete the last a row from the matrix.

It will be noted that the subsequent steps which are for the rows associated with the interaction part of the model are somewhat more complex. The row associated with the  $ik$  subscripts in this part of the  $T_R$  matrix is obtained by the formula below in which each term represents a row:

$$g_{a_{ik}} = g_{a_{iq}} - g_{a_{pk}} + g_{a_{pq}}$$

where  $i = 1, 2, \dots, p$

$k = 1, 2, \dots, q$

For this example  $p = 3$ ,  $q = 3$ . The rows obtained are indicated below:

$$g_{a_{11}} = g_{a_{13}} - g_{a_{31}} + g_{a_{33}}$$

$$g_{a_{12}} = g_{a_{13}} - g_{a_{32}} + g_{a_{33}}$$

$$* g_{a_{13}} = g_{a_{13}} - g_{a_{33}} + g_{a_{33}}$$

$$g_{a_{21}} = g_{a_{23}} - g_{a_{31}} + g_{a_{33}}$$

$$g_{a_{22}} = g_{a_{23}} - g_{a_{32}} + g_{a_{33}}$$

$$* g_{a_{23}} = g_{a_{23}} - g_{a_{33}} + g_{a_{33}}$$

$$* g_{a_{31}} = g_{a_{33}} - g_{a_{31}} + g_{a_{33}}$$

$$* g_{a_{32}} = g_{a_{33}} - g_{a_{32}} + g_{a_{33}}$$

$$* g_{a_{33}} = g_{a_{33}} - g_{a_{33}} + g_{a_{33}}$$

- (5) Subsequently remove from the matrix the rows corresponding to  $g_{a_{iq}}$ ,  $g_{a_{pk}}$  and  $g_{a_{pq}}$ . These are indicated by an asterisk (\*) in the above list.

The remainder of the  $T_R$  matrix remains unaltered.

The loading routine for the  $T_R$  matrix requires the omission of the rows prescribed in the steps above. It is necessary however that the remaining rows be in proper sort. The row numbers must be in ascending order but it is not necessary that they be consecutive.

The Phase II Program consists of Part 1 and Part 2. The function of Part 1 is to read the  $T_R$  matrix into the machine. This is the second level of processing. If the  $T_R$  matrix is already on the drum then this part of the program need not be used, i.e., do not place Part 1 in the Read Hopper.

The function of Part 2 is to perform the multiplication  $T_{LATR}$ . This part assumes the  $T_R$  matrix is already on the drum.

It is necessary that the A matrix be preceded by a header card since the A matrix may be in fixed-point or one of the two floating-point formats. The header card format is the same as for the  $T_R$  matrix. The header card and the A matrix are given in Appendix A, Table 8.

The order of assembly for Phase II is as follows:

Part 1

- (1) Program: The first and second cards are drum clear cards. The third, fourth and fifth cards constitute the seven-per-card load routine. The next seventeen cards constitute the actual program which is followed by a transfer card (to transfer out of the seven-per-card load routine). The first five cards

and the last card are load cards.

- (2) Blank card
- (3) Header card (non-load): See Appendix A, Table 10.
- (4)  $T_R$  matrix (non-load)

#### Part 2

- (5) Program: The first, second and third cards constitute the seven-per-card load routine. The next thirty cards constitute the actual program. This is followed by a transfer card (to transfer out of the seven-per-card load routine). The first three cards and the last card are load cards.
- (6) Header card (non-load): See Appendix A, Table 8.
- (7) A matrix (non-load)

Three decks of cards constitute the output of Phase II. They are in non-load normal floating-point form. The deck number is punched in card column one. The designation is as follows:

Deck 1 is the intermediate product  $AT_R$ .

Deck 2 is the  $T_L$  matrix which is obtained by the program from the  $T_R$  matrix.

Deck 3 is the product  $T_L AT_R = R | G$ .

The output format is:

Word 1 wiiiiyyzz where w is the deck number

iieee is the corresponding identification in columns

two through six of Word 2 in the A matrix header card

yy is the row number

zz is the card number for the row specified by yy

Words 2 through 8 are the elements of the matrices  
Decks 1, 2 and 3 for this sample case are given in  
Appendix A, Tables 11, 12 and 13 respectively.

### Operating Instructions

#### Phase I

The instructions for Phase I are in Appendix B of this thesis.

#### Phase II

- (1) Assemble the programs and data as described above and place in the Read Feed Hopper of the machine.
- (2) Set the Console: 70 1951 xxxx + Control Run  
Programmed Stop Half Cycle Run Error Stop  
Display Program Register Overflow Stop
- (3) Place a standard (80-80) board in the 533 Read Punch Machine.
- (4) Clear the Punch Hopper and load it with blank cards.
- (5) Depress Computer Reset, Program Start and Read Feed Start in that order. This will cause the machine to read in the program and data. The machine will calculate and punch decks 1 and 2 and will halt with 01 1212 1926 in the Program Register.
- (6) Remove decks 1 and 2 from the Punch Hopper; discard the first and last cards which are blank.
- (7) Place decks 1 and 2 from step 6 above ( $AT_R$  and  $T_L$ )

respectively) in the Read Feed Hopper without disturbing the order.

- (8) Depress Program Start. At this point the machine will complete the calculation and punch  $T_{LATR} = R | G$ , i.e., the reduced normal equations.
- (9) Remove the cards from the Punch Hopper. Discard the first and last cards which are blank.

This completes the operations for Phase II. The  $R | G$  matrix is left on the drum in the proper location for Phase III.

## CHAPTER III

### THE PROGRAM: PHASE III

#### Procedures for Processing

The Phase III Program consists of Parts 1, 2, 3, 4 and 5.

The function of Part 1 is to read the  $R | G$  matrix into the machine. This is the third level of processing. It is necessary that this part of the program be followed by a control card. The control card permits the machine to omit the reading of the  $R | G$  matrix, i.e., if the  $R | G$  matrix is already stored in the machine with the first element in location 0001 and the elements in the floating-point mode x.xxxxxxx51. The format for the  $R | G$  matrix control card is given in Appendix A, Table 14. The control card for this case is given in Appendix A, Table 15.

The function of Part 2 is to invert the R partition of the  $R | G$  matrix. This is the fourth level of processing. There is no additional control required for Part 2.

The function of Part 3 is to punch the inverse of the R matrix and the solutions. The inverse and solution  $R^{-1} | B$  are punched out only if the console is set minus (-). The matrix  $R^{-1} | B$  for this case is given in Appendix A, Table 16.

The function of Part 4 is to punch segments of the solution vectors (beta vectors) of the  $R | G$  matrix and the asso-

ciated control cards for Part 5. These vectors and control cards must be removed from the Punch Hopper and be placed in the Read Feed Hopper behind the program for Part 5. The beta vectors and control cards are shown in Appendix A, Table 17, and the formats are shown in Tables 18 and 19 respectively.

The function of Part 5 is to invert the segments on the diagonal of  $R^{-1} | B$  and to calculate and punch the scalar value associated with the reduction in the sum of squares to each attribute. The scalars for this case are shown in Appendix A, Table 20, and the format is shown in Table 21.

The order of assembly for Phase III is as follows:

#### Part 1

- (1) Program: The first card is a program title card. The second and third cards are drum clear cards. The fourth, fifth and sixth cards constitute the seven-per-card load routine. The next twenty-three cards constitute the program. The first six cards and the last card are load cards. These are followed by a blank card which precedes the following specified cards.
- (2) Control card (non-load): See Appendix A, Table 15
- (3)  $R | G$  matrix (non-load)

#### Part 2

- (4) Program: The first thirty-one cards constitute the actual program. These cards are followed by a transfer card (the only load card) to transfer out

of the seven-per-card load routine.

Part 3

- (5) Program: The first thirty-three cards constitute the actual program. These cards are followed by a transfer card (the only load card) to transfer out of the seven-per-card load routine.

Part 4

- (6) Program: The first thirty-five cards constitute the actual program. These cards are followed by a transfer card (the only load card) to transfer out of the seven-per-card load routine.

Part 5

- (7) Program: The first forty cards constitute the actual program. These cards are followed by a transfer card (the only load card) to transfer out of the seven-per-card load routine.
- (8) Beta vectors and control cards (output from Part 4)

Operating Instructions

Phase III

- (1) Assemble the programs and data as described above, except for step 8, and place in the Read Feed Hopper of the machine.
- (2) Set the Console: 70 1951 xxxx ± If the Console is set minus (-) the machine will punch  $R^{-1}|B$ . If the Console is set plus (+) the machine will not punch  $R^{-1}|B$ . Programmed Stop Address Anything

Half Cycle Run Display Program Register

Overflow Stop Error Stop Control Run

- (3) Place a standard (80-80) board in the 533 Read Punch Machine.
- (4) Clear the Punch Hopper and load with blank cards.
- (5) Depress Computer Reset, Program Start and Read Feed Start in that order. This will cause the program to read in the reduced normal equations and calculate the inverse of the coefficient matrix and the solution vectors.
- (6) If the Console is set minus (-) the program will punch  $R^{-1} | B$  and halt; 01 1999 1999 will appear in the Program Register. Remove the punched cards from the Punch Hopper. These cards cannot be used for any of the subsequent machine calculations.
- (6a) If the Console is set plus (+),  $R^{-1} | B$  will not be punched out. The program will operate without interruption and step 7 will be automatic.
- (7) Depress Program Start. At this point the program will punch the segments of the beta vectors and the associated control cards.
- (8) Remove the punched cards from the Punch Hopper. Discard the first and last cards which are blank and place the remaining punched cards behind the last card of the program (Part 5). The program will continue to completion of Phase III.

## CHAPTER IV

### SUMMARY OF INSTRUCTIONS AND LIMITS OF MAGNITUDE OF MATRICES

#### Instructions

##### Phase I

Console Setting: 70 1951 3000 + Programmed Run  
Half Cycle Run Control Run Error Stop  
Address Selection xxxx Display Program Register  
Overflow Stop  
Input: Header card (load)  
X | Y matrix (non-load)  
Trailer card (load)  
Output: A matrix

##### Phase II

Console Setting: 70 1951 xxxx + Programmed Stop  
Half Cycle Run Control Run Error Stop  
Address Selection xxxx Display Program Register  
Overflow Stop  
Input: Header card (non-load). Insert behind the  
blank card which separates Parts 1 and 2.  
Leave the blank card in the program.  
 $T_R$  matrix (non-load)  
A matrix (non-load)

Output:  $AT_R$  matrix (non-load)

$T_L$  matrix (non-load)

Note: At this point the program will halt and  
 01 1212 1926 will appear in the Program Register.  
 Remove the punched cards from the Punch Hopper  
 and discard the first and last cards which are  
 blank. Place this output ( $AT_R$  and  $T_L$  respec-  
 tively) in the Read Feed Hopper, without dis-  
 turbing the order, and depress Program Start.

Output (continued): R | G matrix (non-load)

Programmed Halts: Reason:

#### Part 1

01 1243 1946	$T_R$ matrix out of sort
01 1953 1946	Word 3 of the Header card contains some number other than 0, 1 or 2.

#### Part 2

01 1212 1926	See (Note:) above
01 1243 1946	The matrix being read is out of sort.
01 0003 1946	Word 3 of the Header card contains some number other than 0, 1 or 2.

#### Phase III

Console Setting: 70 1951 xxxx ± If the Console is  
 set minus (-) the machine will punch  $R^{-1} \mid B$ . If the  
 Console is set plus (+) the machine will not punch  
 $R^{-1} \mid B$ .

Half Cycle Run Control Run Error Stop

Address Selection xxxx Display Program Register

Programmed Stop Overflow Stop

Input: Header card (non-load). Insert behind the blank card which separates Parts 1 and 2.

Leave the blank card in the program.

$R \mid G$  matrix

Output: If the Console is set minus (-) the output is  $R^{-1} \mid B$  and the program will halt with 01 1999 1999 appearing in the Program Register.

Note: Remove the output from the Punch Hopper; these cards cannot be used for any of the subsequent machine calculations.

Output (continued): Beta vectors and Control cards

Note: Remove the first and last cards which are blank and place this output in the Read Feed Hopper behind Part 5 of the program.

Output (continued): Scalar values, i.e., reductions in the sum of squares.

Programmed Halts: Reason:

01 1111 1650              The header card specifies the number of rows in the partitions, and the number of rows of the  $R \mid G$  matrix; these two numbers do not agree.

01 1650 1650               $R \mid G$  out of sort

01 1999 1999               $R^{-1} \mid B$  was punched out

### Limits of Matrices

Matrix	Limits (maximum)
X   Y	47 variables, i.e., 47 columns
T <sub>R</sub>	42 x 43 (or no more than 1806 elements)
A	42 x 42
AT <sub>R</sub>	42 x 43 (or no more than 1806 elements)
R   G	(NX + 1)(NX + NY) ≤ 1630 NX is the number of rows in R   G. NY is the number of right hand members.

Note: If NY is 1 then the maximum size of R | G will be 39 x 40. This does not allow T<sub>L</sub>, A and AT<sub>R</sub> to be maximum size.

## APPENDIX A

TABLE V  
PHASE I HEADER FORMAT

Header Card (load card)

Word 1	3010000003
	30           variables
	1           indicates a packed card
	3           words beginning in
	column 11
Words 2, 3 and 4	1111111111, 1111111111, 1111133334 The first twenty-five variables each have one digit. The twenty- sixth through the twenty-ninth variables have three digits each and the thirtieth variable has four digits.

Note: The unused words of the header card may be left blank.

TABLE VI  
PHASE I TRAILER FORMAT

Trailer Card (load card)

Word 1	0000301355 -
	30           variables
	1355 -       built-in control
Word 2	0100020000
	1           punch $X_i X_j$
	2           with two decimal places
	0           do not punch the associated
	quantity
Word 3	2101000000
	2101       is the identification to
	be punched in the output

Note: The unused words of the trailer card may be left blank.

TABLE VII  
X | Y MATRIX FORMAT

Word 1 Identification of each individual observation

Words 2 to 8

Columns	Quantity
11	u
12	$g_1$
13	$g_2$
14	$g_3$
15	$s_{11}$
16	$s_{12}$
17	$s_{13}$
18	$s_{21}$
19	$s_{22}$
20	$s_{31}$
21	$s_{32}$
22	$s_{33}$
23	$s_{34}$
24	$a_1$
25	$a_2$
26	$a_3$
27	$(ga)_{11}$
28	$(ga)_{12}$
29	$(ga)_{13}$

TABLE VII (continued)

Columns	Quantity
30	$(ga)_{21}$
31	$(ga)_{22}$
32	$(ga)_{23}$
33	$(ga)_{31}$
34	$(ga)_{32}$
35	$(ga)_{33}$
36 -- 38	b (age)
39 -- 41	d (initial weight)
42 -- 44	first right hand member (ADG)
45 -- 47	second right hand member (fictitious)
48 -- 51	third right hand member (fictitious)
52 -- 60	Zero
61 -- 80	Blank

Note: Columns 11 through 35 contain either the digit zero or one. The digit one (1) was placed in the column if the corresponding quantity was associated with the observation; otherwise the digit zero (0) was placed in the column.

TABLE XIV

## R | G MATRIX CONTROL CARD FORMAT

The control card (non-load) has the following format:

Columns	1 -- 6	Identification desired in $R^{-1}   B$
	7 -- 10	Irrelevant
	11 -- 12	00 if $R   G$ is on the drum
	11 -- 12	xx (any two digit number other than 00) if $R   G$ is not on the drum
	13 -- 14	NY is the number of right hand members
	15 -- 16	NX is the number of rows in the reduced normal equations $R   G$
	17 -- 18	NP is the number of partitions on the main diagonal of $R   G$
	19 -- 20	N1 is the number of rows in the first partition (or segment) of the reduced normal equations
	21 -- 22	N2 is the number of rows in the second segment of the reduced normal equations
	23 -- 24	etc.

TABLE XIV (continued)

79 -- 80      N31 is the number of rows in the  
                  thirty-first segment of the  
                  reduced normal equations

Note: Punch zeros in the unused columns of the control card if the matrix is partitioned into less than thirty-one segments. The sum of the number of rows of the segments must agree with the number of rows in the reduced normal equations.

TABLE XV

## R | G MATRIX CONTROL CARD

Word 1 6543210000

654321 is identification

0000 is irrelevant

Words 2 to 8

Columns	Punched	Indicates
11 -- 12	01	required to read R   G
13 -- 14	03	three right hand members
15 -- 16	17	seventeen rows in R   G
17 -- 18	09	nine partitions in R   G
19 -- 20	01	one row in the first partition
21 -- 22	02	two rows in the second partition
23 -- 24	02	two rows in the third partition
25 -- 26	01	one row in the fourth partition
27 -- 28	03	three rows in the fifth partition
29 -- 30	02	two rows in the sixth partition
31 -- 32	04	four rows in the seventh partition
33 -- 34	01	one row in the eighth partition
35 -- 36	01	one row in the ninth partition
37 -- 80	Zero	(since the complete card must be punched)

TABLE XVIII  
FORMAT FOR BETA VECTOR SEGMENTS

The beta vectors are read into the machine by the seven-per-card read-in routine which requires the following format:

Word 1	00xxxx000y
	xxxx is the location into which the first word of the corresponding card is to be read.
	y is the number of words in the card.
Words 2 to y	contain the elements of the associated beta vector segment.
Words y to 8	are irrelevant and may contain any number (i.e., residue of the punch band).

Note: Each beta vector segment is followed by a control card. The order of the beta vector segments and the control cards must not be disturbed.

TABLE XIX  
FORMAT FOR CONTROL CARD FOR BETA VECTOR SEGMENTS

Word 1	0000001947 -
	Word 1 causes the seven-per-card load routine to transfer to location 1947.
Words 2 to 8	Irrelevant These words will contain the same numbers as the preceding card punched.

TABLE XX  
SCALARS (OUTPUT)

TABLE XXI  
FORMAT FOR SCALARS

Word 1	wxxxxxyyzz
	wxxxxx is the identification in the R   G matrix control card increased by one in the position which is specified by w.
	yy is the sequential number of the segments of the R <sup>-1</sup>   B matrix.
	zz is the sequential number of the right hand member.
Word 2	The scalar value
Words 3 to 8	Irrelevant

## **APPENDIX B**

## PROGRAM FOR PHASE I

Phase I consists of the Beaton Correlation Routine. The write-up for Phase I as it appears in this thesis is a revision of the write-up which is on file at the Oklahoma State University Computing Center.

This program was designed to calculate the raw sums, raw sums of squares and crossproducts, covariances, corrected sums of squares and crossproducts, means, standard deviations and correlations for a maximum of forty-seven variables. The sum of squares for a variable cannot exceed ten digits.

Note: The drum must be cleared before executing Phase I. The program preceded by two drum clear cards is shown in Appendix A, Table 1.

The size of the variables can range from one digit to four digits and can be either one-per-word or packed; the one-per-word can be either positive or negative, the packed can only be positive.

The output of this program is in fixed decimal point for the raw sums and sums of squares but can be in either the fixed-point mode or the floating-point mode for all other statistics. The floating-point format is 50x.xxxxxxx. The mode is controlled by a trailer card which also specifies the quantities which are to be punched out by this program.

The input for this program consists of a header card,

the data, i.e., the X | Y matrix, and a trailer card. The unused columns of a word must be filled in with zeroes. It is unnecessary to punch the unused words of any input card.

#### Header:

The header card (load card) has the following format:

Word 1            xxy000000z

xx is the number of variables

y is 1 if the data is packed

y is 0 if the data is not packed

z is the number of words used in the header card starting with Word 2

Words 2 to z    where z is defined in Word 1

#### Packed Case:

Each column indicates the number of digits in the associated variable, i.e., column 11 is associated with the first variable, column 12 with the second variable, etc. However, if for some reason all the variables are not on one card a minus (-) sign is used to indicate that there are variables on the following card. In the same manner the first column of the associated negative word indicates the number of digits in the first variable of the corresponding card; the second column, the second variable; etc.

#### Example:

Columns 11 -- 30	(Card 1 has 11 variables)	1223422121 +
		3000000000 +
31 -- 40	(Card 2 has 4 variables)	2223000000 -
41 -- 50	(Card 3 has 2 variables)	2100000000 -

### Unpacked Case:

Each column indicates the number of variables in the associated card, i.e., column 11 is associated with the first card; column 12 with the second card; etc.

### Example:

7570000000 - (Indicates 3 cards with 7 variables on the first card, 5 variables on the second card and 7 variables on the third card)

### Data:

The data X | Y is in fixed decimal point mode. Word 1 is reserved for identification. Words 2 through 8 are for data. Word 1 can be key punched in from column 11 on, variable by variable, with no regard for end of word if all values are non-negative. If the data is unpacked, then no more than seven variables can be punched on a card with each variable in a separate word from 2 to 8.

### Trailer:

The trailer card (load-card) has the following format:

Word 1 0000xx1355 -

xx is the number of variables

Word 2 is used for punch control

0 no punch; 1 punch in float point.

However if the quantity is in fixed-point (see columns 14, 16, 18 and 20 below) the non-zero digit indicates the number of desired decimal places.

The quantities associated with the columns  
in the trailer card are indicated below:

Column	Quantity
11	$\sum X_i$
12	$\sum X_i X_j$
13	Cov. - float
14	Cov. - fixed
15	S. S. Cr. Pr. - float
16	S. S. Cr. Pr. - fixed
17	$\bar{X}$ , $\sigma$ - float
18	$\bar{X}$ , $\sigma$ - fixed
19	Cor. - float
20	Cor. - fixed

Word 3      xxxx000000

xxxx is the identification desired in the  
output

Words 4 to 8   Blank

Output:

The output has the following format (non load cards):

Word 1      xxxxwwyyzz

xxxx is problem identification (copied from  
the trailer card)

yy is the row number in the A matrix

zz is the card number in the row

ww is the code which identifies the asso-  
ciated quantities:

WW	Quantity
00	N
01	$\Sigma X_i$
02	$\Sigma X_i X_j$
03	Cov. - float
04	Cov. - fixed
05	S. S. Cr. Pr. - float
06	S. S. Cr. Pr. - fixed
07	$\bar{X}$ - float
08	$\bar{X}$ - fixed
09	$\sigma$ - float
10	$\sigma$ - fixed
11	Cor. - float
12	Cor. - fixed

Refer to page 4 of this thesis for a discussion of how Phase I was used in processing the sample problem.

**VITA**

Lee Vernon Brown

Candidate for the Degree of  
Master of Science

Thesis: A PROGRAM FOR LEAST SQUARES ANALYSIS OF DATA WITH  
UNEQUAL SUBCLASS NUMBERS

Major Field: Mathematics

Biographical:

Personal Data: Born in Grainola, Oklahoma, April 17,  
1924, the son of John Y. and Arizona Brown.

Education: Attended grade school and junior high  
school in Avant and Skiatook, Oklahoma; graduated  
from Skiatook High School in 1943; received the  
Bachelor of Arts degree from the University of  
Wichita, Wichita, Kansas, in August, 1949; com-  
pleted requirements for the Master of Science  
degree in August, 1962.

Professional experience: Entered the United States  
Air Force in 1943 and was commissioned as a Bom-  
bardier in April, 1945; taught mathematics in the  
Junior High School, Lawrence, Kansas, from 1949-  
1951; was employed by Beech Aircraft, Wichita,  
Kansas, from 1951-1956; was employed at Douglas  
Aircraft, Tulsa, Oklahoma, from 1956-1959 as a  
Computing Analyst in the Computing Engineering  
Section; worked as a graduate assistant in the  
Computing Center at Oklahoma State University;  
presently an Assistant Professor of Mathematics,  
Evangel College, Springfield, Missouri.
