ACKNOWLEDGEMENTS

First and foremost, I'd like to acknowledge my parents, Jeff and Beth, who provided me a place as a child to develop my interest in the natural world. I really do believe the reason I have a passion for the field of archaeology is due to the countless hours I spent being a kid outdoors collecting up cow bones (and anything else I could find) to hide under my bed, and dreaming up all of the ways stuff may have ended up to be where I found it.

I sincerely thank Dr. Leland Bement for his thoughtful dedication to the growth of my understanding of science, and the leadership and patience he continues to offer toward my evolution as a grown man. Lee also provided unlimited access to his collections to me for over a decade, and the gesture and lessons learned have not gone unappreciated. Thanks are due to my committee members, Dr. Don Wyckoff, Dr. Patricia Gilman, and Dr. Lesley Rankin-Hill, for contributing input on my reading copies and for teaching me early in my professional development that archaeology is about human behavior. Thanks are also due to Dr. Linda Wallace who greatly aided my understanding of grassland environments. Special thanks are due to Dr. George Morgan whom with I started this process of understanding elements in teeth and asked all of the really good questions that will be the focus of my future research. I was lucky enough to have George back on my committee as a symbol of having come full circle.

I would like to thank the National Science Foundation and those who reviewed my proposal for granting the funding of the research described in this dissertation (NSF Grant 0535599, 2005).

There are many folks to thank who provided access and tooth samples including: Barney Coppedge and Marv Jensen at the Vermejo Park Ranch; Jeff Gossage and Blake at the Medano-Zapata Nature Conservancy; unnamed folks at the Hugh S.H.A.P.E. Bison Ranch and Dr. Solvig Turpin for collecting and freezing those stinky mandibles, and allowing me to saw them up in her garage; Eva Horne at the Konza Prairie Biological Station; Linda Hubalek at the Smoky Hill Bison Company; Bob Hamilton at the Tallgrass Prairie Preserve; Dr. Eileen Johnson and Jennifer at Texas Tech University; and Dr. David Meltzer at Southern Methodist University. Without these wonderful donations of time and materials, this research would not have been possible. And, see, the laser didn't blow them up!

I owe many, many thanks to John Lansdown at the University of Texas for helping me begin to understand and use the laser ablation technique, and to Dr. Hector Ness and John Dudgeon at IIRMES for assistance funding the research and help working with the LA-ICP/MS to comprehend how my raw data was obtained and if any of it was useful. Thanks also to Dr. Patrick Livingood for leading me to and instructing me on the wonderful statistical tools that are available online and for free!

Thanks are due to Wanda Downs and Kim Tiger who have assisted me in countless ways over the years and who have, with good humor, helped me keep some of the “interesting” things professors do in perspective. Thank you also to the Oklahoma

Archeological Staff for supporting me in various ways and letting me bounce ideas and questions off of each of you.

Very heartfelt thanks are due to Chris and Amy Cojeen, Lauren O'Shea, and Scott Sundermeyer. Chris and Amy have provided me the opportunities to obtain a wealth of knowledge on applying archaeology that was not afforded me in academia, while making me feel like part of the family. Lauren is the single most inspiring individual I know and I'm proud that she has been a part of my life for over ten years. Her ideas about archaeology and life in general have always been unlimited and unbound; a virtue in any scientific discipline. Scott has been there for me as a true friend throughout the final stages of this research. I'm quite certain that if he had not accepted that role the current dissertation would have not been completed in 2010.

In the sport of baseball, we refer to someone who has a perfect swing as a "textbook" batter. Thanks to the only "textbook" archaeologist I know, Natalie Graves, for her support, discussion and review of this dissertation, and love. I love you too!

ABSTRACT

Modern and prehistoric bison teeth from the Southern Plains are analyzed to assess the interrelatedness of *Bison antiquus* – an extinct form of the North American buffalo - and human movements between 10,800 and 10,200 years ago. This study uses Laser Ablation Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) to examine the down-tooth distribution of trace elements in enamel of modern *Bison bison* from Colorado, Kansas, New Mexico, Oklahoma, and Texas to define the geographical limits and concentrations of specific minerals. In addition, *Bison antiquus* teeth from Early Paleoindian locales on the Southern Plains are analyzed. The modern bison enamel provides an elemental map upon which the movements of extinct herds are assessed. *Bison antiquus* herd movement and structure can be linked to human adaptive strategies on the Southern Plains. Human hunting tactics shifted from a moderately specialized approach to highly specialized bison hunting around 11,000 B.P. The presence of predictable migratory and residential bison herds in the Southern Plains was likely a catalyst for specialized bison hunting.

CHAPTER 1: UNDERSTANDING HUMAN-PREY RELATIONSHIPS

We need not look far to discover that the connection between humans and animals is so embedded in our religions, cultures, and ideals that when we stop to look we find that information regarding such relationships abound. It makes sense then that scientists have taken an interest in observing and explaining past and present symbiotic human and animal behaviors. Archaeologists, specifically, have diligently produced a boundless number of inferences about past humans and their dealings with nature across the globe.

In his book, *Survival by Hunting: Prehistoric Human Predators and Animal Prey*, Dr. George C. Frison (2004:xiii) expressed concerns about young archaeologists who would not have “an intimate knowledge of animal habitats and behavior, expertise in the use of weaponry and tools, and experience acquired through both hunting and predator control” from which to understand past procurement strategies (**Figure 1.1**). Human and animal behaviors (as well as the interaction between them), though, have changed over the course of human occupation in North America, so it is to our benefit as archaeologists that we are able to couple our personal experiences with fine scale analyses of prey animals to infer past procurement strategies.

Figure 1.1 Confused archaeologist having trouble with identifying the difference between and the nature of the bison and the cow.

This thesis examines the trace minerals in Folsom-age (10,800-10,200 radiocarbon years before present (B.P. from this point forward)) bison teeth to determine where geographically these animals grazed over the period of tooth development over approximately one year. The results of this analysis are used to develop a model of human mobility that addresses the degree to which early hunter-gatherers on the U.S. Southern Great Plains (**Figure 1.2**) structured movements around bison. By meshing the early concepts of cultural ecology with human adaptive strategies, I provide a detailed example of how humans spatially and seasonally organize themselves to acquire resources. A study of this nature is of specific interest to the numerous disciplines concerned with reconstructing past ecological relationships and predicting future global changes.

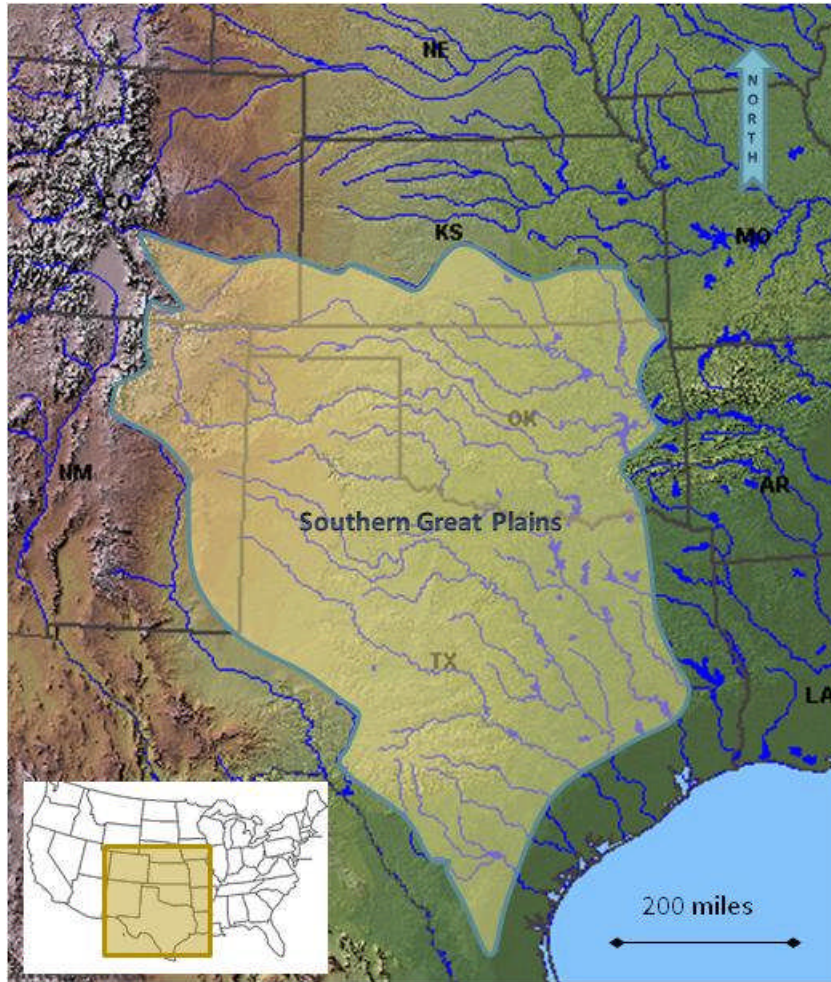

Figure 1.2 The U.S. Southern Great Plains study area.

THE PARADIGM

The manner in which anthropologists choose to view human movement has profound effects on how models of present and past human settlement systems are observed. The current study is interested in linking resource structure to human mobility, and therefore, only works if the decisions humans make are in some way related to the environment in which they live. Interest in the relationship between human culture

and the environment has been of primary interest to many social scientists (e.g., Daniel 1950; Kroeber 1939; Steward 1955; Worsaae 1849; Wissler 1926). In anthropology, the interest in understanding how prehistoric cultures operated in relation to their natural environment has its roots firmly planted in early Functionalist thought. From the mid-1800s to present day, a group of Scandinavian archaeologists have studied archaeological finds as they relate to paleoenvironmental settings in an effort to identify how changing environments effected flora, fauna, and human land use (Trigger 1989:247-250). Consistently identifying the relationships between a group of humans and their environment, however, has been difficult for anthropologists (Kelly 1995:39). Early theoretical paradigms focused on subsistence technology and how this technology changed in relation to different environmental conditions and yielded the obvious conclusion that a society will adapt to its natural environment. Kroeber (1939:1) noted, however, that cultures would not be produced by a given natural environment. More recent studies have focused upon making explicit use of how evolutionary processes structure human societies in response to environmental conditions (e.g., Boone and Smith 1998; Smith and Winterhalder 1992; Winterhalder and Smith 1992), and are the focus of the following discussion.

Our cultural capabilities rely on learning and experience within a given environment. Assuming humans forage optimally within that environment, the mechanisms for human adaptive optimization are rational choice and natural selection (Winterhalder and Smith 1992:20). Rational choice pertains to “a powerful element of human adaptation” that implies that there are preexisting preferences for options with high-payoffs stemming from a history of natural selection (Winterhalder and Smith

1992:21). Using an optimal foraging research approach can relate behavioral patterns to ecological factors. Clearly, a correlation can be made between behavioral variability and the environment.

A major critique of evolutionary ecology theory by some social scientists is that by applying environmental factors to explain human behavior, anthropologists are in fact supporting environmental determinism. No aspect of the environment solely determines human behavior (Winterhalder and Smith 1992:20). The environment does not limit human behavior; rather, it establishes the payoffs of certain behavioral patterns. Winterhalder and Smith (1992:20) believe that great contributions to our understanding of process in cultural evolution will be made by archaeological studies focusing on the adaptive level of human populations within specific environmental contexts that take into consideration different variables such as technology, social structure, and economic organization will make real contributions to our understanding of process in cultural evolution.

One major difficulty anthropologists have had in applying evolutionary concepts to socio-cultural phenomena is that cultural traits are not bound to genetic mechanisms; hence, different rules govern the rate, direction, and mode of their transmission. Natural selection influences behavioral patterns through genetic and cultural evolution. Most anthropologists believe that genetic differences among individuals do not seem to affect their foraging behaviors (Winterhalder 1981a:16). Behavioral variability appears to be consciously or unconsciously adopted by individuals

(Winterhalder 1981a:16). Thus, the adaptive effect will remain the same, regardless of whether the change is biological or cultural.

Optimal foraging theory is frequently criticized for not taking into account those food items collected for their non-food value (Kelly 1995:110). Cultural traditions can outrank an optimal resource. Optimization models make predictions about the value and return rates for certain resources. Consequently, if an animal was not exploited for subsistence purposes, their purpose for being in the archaeological record may not be fully understood. For example, dogs often were utilized as a food source and as beasts of burden (Kelly 1995:110). Therefore, the optimization model used to evaluate their utility as a resource would have to be based on their optimal value as food source as well as their optimal value as a pack animal (Kelly 1995:110).

Ideally, optimal foraging theory analyses should evaluate behaviors over a relatively long time interval in order to accurately represent their aggregate effect on the organism (Winterhalder 1981a).

Evolutionary ecology theory is used to make sense of particular aspects of human adaptation that are distinct steps toward reaching a goal, which in this case is the economic specialization on bison. Identifying species of plant and animals exploited by a group of people in a specific region only provides part of the information needed to assess cultural-ecological relationships. No environment is completely constant from year to year, and people cope with these variations in resource availability in different ways. Optimal foraging theory is applicable to many aspects of human behavior. Among the variables that directly affect optimal adaptation are group size,

climate, physiography, the abundance of resources, and butchering patterns which, in the present case, are all related to procuring bison.

Particular human behavioral adaptations can be employed optimally to support a population dependent primarily on exploiting bison. According to Bamforth (1988:16), people will form special task groups in order to successfully obtain food for a larger social group and those people will come to rely on seasonal food storage. Additionally, because different foods become available at different seasons, both hunter-gatherer and agricultural or pastoral society group size can vary seasonally (Driver 1990:13). The communal (a group size increase) bison hunt was an integral part of a seasonal subsistence pattern for almost all of the groups of people who once resided on the Plains.

Bamforth (1988) offers a useful summary of various ethnographic, ethnohistorical, and archaeological research of the practice of communal hunting on the Plains.

“In preparation for the communal hunt, a large number of people gathered into a camp at a predetermined location under the direction of a shaman or other temporary leader. At least in recent times these hunts occurred primarily in the fall. The locations for these gatherings were chosen because they were close to specific places that were well-suited to mass kills of bison, either because of convenient topography or because traps had been constructed there. There is evidence people “geared up” in preparation for these aggregations by visiting quarries and manufacturing the projectile points and butchering tools needed for the hunt. Activities in the communal encampment

included both a wide range of social and ritual activities and the preparation for the kill. This preparation included such activities as sending scouts out as much as 40 to 50 miles to locate and lure in the herds and preparing the equipment needed to process the huge volumes of meat and hides to be produced. Once the drive was accomplished, using any of a variety of relatively well-known methods of entrapment, it was necessary to kill the animals that had not died in the stampede and then to butcher the carcasses. Butchering at the immediate site tended to remove the major meat units for transport to a secondary processing area or to a camp to be prepared and dried; this meat was often wrapped in the animal's own hide for transport. Processing the products of even a relatively small kill took several days" (Bamforth 1988:9).

Knowing that a group of people communally hunt bison only tells archaeologists part of the story—understanding this adaptation is also revealed by a specific pattern of bison exploitation at a particular time and place on the Plains. In order to focus on the predictability of an animal resource, understanding whether large numbers of bison or just one or two bison were taken during a single hunting episode is necessary. If hunting is a successful part of a human subsistence strategy, surplus animal resources must be returned and shared. This can be accomplished by being a more efficient killer of a single prey, killing large prey, or killing more prey per single hunting episode (Steele and Baker 1993:24). Multiple predation occurs when a task force or communal hunting group takes multiple animals in order to increase the number of animal resources exploited in the most efficient manner possible.

One must also consider the importance of varying search and handling time costs could among different groups of people at different times because local patterns of productive resource distribution can vary from season to season and from year to year. There are time constraints on hunting and foraging excursions. When travel time is high the amount of field processing will be low and either a smaller amount of the load will be processed, or, to a lesser extent, the entire load will be processed (Metcalf and Barlow 1992:351). Therefore, when a resource such as bison are procured at greater distances we can assume mixed loads of processed and unprocessed bones will be transported back to the residential camp or village.

The paradigm, whether one calls it evolutionary ecology, behavioral ecology, or what have you, provides a framework from which to determine how ecological and social factors influence and shape behavioral flexibility within and between human populations. Literally thousands of anthropologists have explained and summarized behavioral ecology, and numerous recent studies are available regarding the topic (see the Human Behavioral Ecology Bibliography maintained by Kermyt G. Anderson, <http://faculty-staff.ou.edu/A/Kermyt.G.Anderson-1/HBE/>), so this manuscript will refrain from providing yet another lengthy lecture. What this paradigm offers to the current study is a methodology that will help us understand how “hunter-gatherers made decisions about interacting with their environment and how those decisions affect the transmission of cultural traits (Kelly 1995:63).”

Evolutionary ecology theory has great potential for addressing many micro-economic optimization questions about how foragers arrive at certain subsistence decisions.

Some archaeologists have adopted an evolutionary ecological approach to help explain human behavior, particularly emphasizing approaches associated with optimal foraging theory, because this approach examines the interrelationships between environmental factors and human adaptations. The physiography and climate of a specific environmental region will determine the kinds, numbers, distributions, and adaptations of plants and animals in that region, making it possible to predict spatial and temporal patterns of resource availability (Bamforth 1988:17). Temporal patterns refer to both seasonal and annual changes of availability, and spatial patterns refer to where in a given area those resources can be found (Bamforth 1988:17). The tasks of obtaining resources require that decisions must be made about how, when, and where a group of people should direct their procurement activities, and will thus determine the nature of their subsistence economy (Jochim 1981:114).

Optimal foraging theory provides anthropologists with models aimed at reconstructing the “on-the-ground decision-making process of foraging” (Kelly 1995:97). This theory is concerned with these often overlapping questions:

- Diet breadth and choice of items;
- Optimal patch choice or where in the spatial environment the forager will seek food resources;
- Optimal patterns of movement and time allocation during foraging; and
- Foraging group size, meaning the circumstances in which foragers will form groups for pursuit of food resources (Winterhalder 1981a:14).

Regarding resource acquisition, optimization pertains to the efficiency, in time or energy costs, with which subsistence activities are performed, with the assumption that increased efficiency relative to a standard of performance leads to an increase in fitness (Winterhalder 1981a:15). Predictions about human adaptations based on energy optimization assumptions provide archaeologists with a realistic approach to analyzing food-getting behavior.

Models of optimal diet are concerned with selectivity (Winterhalder 1981a:23). A forager can be a “specialist” or a “generalist” when faced with selecting widely or narrowly within the realm of potentially exploitable resources (Winterhalder 1981a:23). Optimal diet models can identify, analyze, and rank forager resource selectivity to reveal decisions people made about which resources to exploit in order to maximize their net rate of energy gained within specific environmental and cultural settings (Winterhalder 1981a). Optimal foraging theory recognizes a clearly defined set of concepts that describe environmental conditions. Three general characteristics used to describe environmental conditions include patchiness, productivity or abundance, and predictability (Bamforth 1988).

Optimal diet models must define the grain patchiness of the environment. An environment can be either patchy, having heterogeneous or a mosaic of resources, or it can be uniform, having well-mixed, similar, evenly distributed resources (Winterhalder 1981a:23). Winterhalder (1981a:23) defined grain as a relative measure determined by comparing environments or assessing the behavior of an organism or population. Winterhalder (1981a:23) explains that humans take advantage of their

environment in a fine-grained manner by structuring their daily activities so as to encounter and exploit different patches in proportion to which they occur. Humans that exploit their environment in a coarse-grained manner choose to take specific resources from a heterogeneous environment in an unbalanced way (Winterhalder 1981a:23). By assessing the behavior of a population in a specific environment, the selectivity of procuring a resource can be determined.

Productivity or abundance is measured by the total floral and/or faunal biomass produced in a region (Bamforth 1988:17). This total may fluctuate for various reasons, including the time of year (seasonality), climate changes, and the nutritional condition of the biomass, which may not coincide with the actual population of a particular local biomass (Bamforth 1988). On the Plains, bison are a high-quality protein resource, and archaeological evidence reveals the importance and abundance of this particular faunal biomass. Bison population densities are determined by regional forage production, and these animals will move over the course of the year to familiar areas, depending on the seasonal distribution and density of their preferred forage (Bamforth 1988:52). The degree to which resources are clumped rather than dispersed in space is directly related to the patchiness of their environment.

In this study, the concept of patch as a spatial unit whose productivity varies from season to season and from year to year is used. Bison herd composition varies according to the patchiness of a particular region. The patchiness of an environment can be due either to “differences in the number of areas suitable for occupation by a herd or by differences in ungulate adaptations causing differing degrees of

aggregation” (Bamforth 1988:19). As a result, the degree of patchiness is likely to vary on a seasonal basis.

Predictability refers to the temporal pattern of resource distribution in a particular region (Bamforth 1988:18). Foragers do not randomly search an area for food; instead, they know where they are going before they leave the village in search of subsistence resources. People do not have the ability to constantly predict the environment on a day-to-day basis; instead, they operate with “complete information” about their environment by acting in terms of strategies that they think will have a high probability of success (Kelly 1995:97-98). They have a knowledge base that is sufficient to allow them to predict with a certain amount of probability the outcome of a particular choice (Kelly 1995; Winterhalder 1981a). For example, fall is the season when bison herds are at their peak of good health; thus, hunting bison in the fall would predictably be the best time for acquiring the highest quality protein yields.

High quality protein acquired by an individual is often determined by the availability of resources. One paradigm, the diet breadth model, offers archaeologists a way to predict what resources were exploited to what degree in order to increase the reproductive fitness of the individual and their exploitive strategies. Hunter-gatherer diets are the products of a decision-making process that takes the cost of acquiring resources into account (Kelly 1995). Resources are ranked based on the amount of energy received in relation to the time and energy necessary to acquire them (Bettinger 1991; Winterhalder 1981a, 1981b). Hunter-gatherers made choices about

what kind of food to procure and eat by determining the net energy value of each item to reveal subsistence information, such as the relative proportions of various foods.

In order to increase, population size increases force people to travel farther in order to obtain adequate resources, so the efficiency of individual foragers to maximize their energy must also increase. If resources are mobile and clumped, such as bison, the optimal strategy is aggregation of the foraging population at a central location (Winterhalder 1981a:31). In this case, increase of travel does not refer to the entire society following mobile resources from location to location. Rather, as populations aggregate into larger residence groups, resources are procured over a larger area by means of using some sort of group-hunting strategy.

Group organization is an optimal behavioral solution to an adaptive problem. There are many advantages to using a group foraging strategy to procure a particular resource. One such advantage is that a group can more effectively exploit large prey, such as bison, by using cooperative search and pursuit methods (Winterhalder 1981a:30). In addition, a group can better defend their territory for exclusive use of particular resources (Winterhalder 1981a:30). Another potential advantage is that a specialized foraging group could monitor a larger area and then exchange information regarding resource composition and distribution at a central location (Winterhalder 1981a:30). According to Winterhalder (1981a:32), when the distribution of a resource—such as bison—is aggregated and mobile, their location is unpredictable. Hence, being able to obtain information regarding herd location at one central place would be advantageous to the success of those foragers.

Behavioral ecology aids in our understanding of environmentally-based decisions by defining analytical limits, or assumptions, to a unit of interest. Under this paradigm one may identify adaptive goals, significant environmental features, and the kinds of behavioral optimization decisions specific to a human group by assuming that organisms focus on consuming the most energy while expending the least amount of energy. The immediate goal of the current study, then, is to identify how the spatial and temporal distribution of bison shaped the behavior of Folsom-age hunter-gatherers by assuming these past humans made decisions to minimize cost and maximize profit. Obviously, cultural traditions can outrank a behaviorally optimal decision. Franz Boas (1955:9) wrote,

“No people known to us, however hard their lives may be, spend all of their time, all of their energies in the acquisition of food and shelter, nor do those who live under more favorable conditions and who are free to devote to other pursuits the time not needed for securing their sustenance occupy themselves with purely industrial work or idle away the days of indolence”.

Although Boas was initiating discussion regarding esthetic values, a very strong point is made that humans make decisions independent of basic biological needs. For this study, though, by assuming bison were a key resource to Folsom-age hunter-gatherers and these people made decisions based on the procurement of bison because the behavior was optimal, we may evaluate whether or not optimization was indeed occurring.

WHAT ARE THE BIOLOGICAL ADVANTAGES OF MOBILITY?

This investigation assumes that there is a direct cause and effect relationship between land use strategies and the distribution of resources across landscapes, and that these decisions would be optimal. Although little attention has been given to the benefits of human spatial organization to reproduction and fitness (survival), a consideration of optimal behavior has to be that the decisions are largely advantageous biologically. Movement patterns evolve among animal species in response to diverse ecological pressures (Dobson 1982). The fitness of an individual is dramatically influenced by its selection of a place (Alcock 1977), and particular movement patterns will be selected if they are imperative to reproduction or survival (MacArthur 1972). Pease and Lande (1989) stated the biogeography of a species is determined by evolution and movements of populations. They suggested the distribution of a species is often more malleable than its morphology or environmental tolerance.

There are several types of population movement or distribution as discussed by biologists: dispersal, migration, limited migration, and dispersion and convergence. Dispersal is an important process for improving a population's ability to respond to changing environments. Dispersal has been defined as: (1) travel by individuals beyond their home range boundaries when they do not return (at least in the short term) as they would after brief excursions (Stenseth and Lidicker 1992); (2) individual movements out of an area larger than a home range with no predictable return (Bunnell and Harestad 1983); and (3) one-way movement by a population with no predictable direction (Sinclair 1992). Dispersal plays a major role in population

regulation (Lidicker 1975) and spatial distribution (Taylor and Taylor 1977). Species that disperse with a low rate of return likely subsist in habitats subject to a high deterioration rate, but low movement cost, possibly due to short distances between suitable habitat niches (Baker 1978). According to Murray's "rule of dispersal" (Murray 1967), individuals move no further than the first suitable uncontested site and no further – assuming the disperser spends no longer than necessary searching for an empty location because of the risk of travel or cost in time – or they disperse to avoid sharing home ranges. Selection favors non-dispersal in the absence of competition, but when competition exists, individuals are pressured to disperse (Waser 1985). Instead of attributing dispersal to a single cause, Dobson and Jones (1985) stated that even if there is one primary cause, other factors may contribute to the magnitude of dispersal. For dispersal to be advantageous, fitness gained from exploiting new areas must exceed the costs of moving.

Migration, another type of movement, is the incursion from one spatial unit to another (Baker 1978). A definition that includes a return component is used most consistently by vertebrate biologists (Stenseth and Lidicker 1992), thus distinguishing it from dispersal. To be adaptive, migratory movements must involve a change in environment, or travel over an "ecological distance" from one environment to another (LeResche 1974). Species with a high incidence of return migration should be those adapted to spatially separate habitat types that fluctuate in relative suitability (Baker 1978). Many ungulates have evolved in grassland, desert, or tundra regions where food availability is highly seasonal or erratic because of drought or snow cover. Messier et al. (1988) considered the increasing energy expenditures for migration as a

possible regulatory factor for the expanding George River caribou herd. In African grasslands, mammal diversity is low, large concentrations of animals are typical, and long distance seasonal migrations are common (Baker 1978). In transitional zones between grassland and forest (i.e. savannah), species diversity is relatively high, animals are not highly concentrated, and migration is rare. When it does occur, migration is for relatively short distances. Species such as wildebeest (*Connochaetes taurinus*), and caribou/reindeer (*Rangifer tarandus*), which are known for long distance mass migrations, typically also have populations that remain sedentary (McNaughton 1985). Migrants may share ranges with residents at certain times of the year. In the Ngorongoro Crater, Tanzania, there are abundant year-round food and water resources and resident wildebeest do not seem compelled to migrate (Talbot and Talbot 1963).

Many migrations occur during transitions between seasons (winter/summer at high latitudes and wet/dry seasons in the tropics) indicating this may be a response to changes in resource availability. Rapid, long distance movements are characteristic of large herbivores that evolved in grassland ecosystems. McNaughton (1985) described the Serengeti region of East Africa, comprised of 27 ungulate species of over three million individuals. The open grasslands receive low annual precipitation that support shortgrass, whereas wooded grasslands receive higher rainfall that support tall, highly lignified grasses. The primary grazers are wildebeest, zebra, Thomson's gazelle (*G. thomsonii*), buffalo and topi (*Damaliscus korrigum*). Annual movements occur in nomadic herds of wildebeest, Plains zebra (*Equus burchelli*) and eland (*Taurotragus oryx*). Although most gazelle (*Gazella spp.*) are nomadic, they travel shorter

distances. Buffalo, topi and gazelle occur as resident herds throughout the savannas. Impala, topi, hartebeest (*Alcelophus buselaphus*) and giraffe (*Giraffa camelopardalis*), which include browse in their diet, remain in wooded grasslands year-round (Baker 1978). Some eland also remain, while others migrate with zebra herds. Among seasonal migrants, relatively little mortality occurs through starvation, but non-migrants such as impala, giraffe, kudu (*Tragelaphus strepsiceros*) and waterbuck all experienced considerable starvation mortality at the end of a dry season in South Africa (Hirst 1969). Wildebeest migrate to open grassland for the wet season to feed on shortgrasses, which are easily digestible and nutrient rich (Fryxell et al. 1988). When water sources evaporate during the dry season, and the food value of tropical grasses declines (Sinclair 1974), wildebeest must migrate to wooded grasslands for water and green grass. Migration during the dry season by White-eared kob (*Kobus kob leucotus*) in Boma National Park, Sudan, allowed access to green grass and water when these resources were scarce elsewhere in ecosystem (Fryxell and Sinclair 1988b). Because Lechwe antelope (*Kobus spp.*) feed on floodplain grasses and herbs, movements coincided with the annual expansion and contraction of flood waters across broad river basins (Fryxell and Sinclair 1988b). These animals disperse during flooding, and then converge when waters subside. In southern California, migratory female Mule deer (*Odocoileus hemionus*) used habitats with higher forage quality than non-migratory deer (Nicholson et al. 1997). However, migrants were exposed to increased predation during the seasonal movements and experienced higher mortality during dry years. Moose typically converge on a common range during winter and disperse into separate ranges during summer

(Hundertmark 1998). For example, an eastern European Tundra moose population formed in the 1950s (Pulliainen 1974) spent the summer on the arctic coast then migrated south to find adequate vegetation for sustenance during winter. In southeastern Norway, migrating moose used habitats of lower quality but higher quantity browse than resident moose (Histol and Kjeljord 1993). No data exists to indicate which strategy provided a nutritional advantage.

Opportunities to use a complementary range of habitats with limited migration distance are afforded in areas with sharp ecological gradients such as mountains. Altitudinal migration is a feature of the seasonal ecology of many ungulate species throughout western North America. Bison (*Bison bison*) use altitudinal gradients in Yellowstone and similar landscapes but used other gradients such as the prairie-parkland transition in the Northern Great Plains (Morgan 1980). The occurrence of migration in many ecosystems around the world suggests there may be common underlying causes (Fryxell et al. 1988). Large herbivores appear to migrate primarily to access high quality food and/or avoid predators, but also as an effective strategy to avoid thermal stress, insect harassment, and contact with disease and parasites.

Dispersion is defined as the internal distribution pattern of a population (Odum 1971), or the distribution of animals in space, ignoring time, since birth (Bunnell and Harestad 1983). As the mean distance between individuals increases through dispersal, changes in dispersion may result in greater clumping, increased randomness, or more even spacing (Stenseth and Lidicker 1992). Convergence decreases the mean distance between individuals. Often, a population undergoes

dispersion when departing on a migration, and convergence on return. If an animal migrates as a herd, then disperses into smaller social units at the destination, herding behavior is assumed to reduce the cost of migration (Baker 1978). Natural selection appears to favor dispersion in animals when food availability is low, or convergence when food availability increases (Leuthold 1977). However, if water or other point resources are limiting, selection seems to favor convergence, whereas dispersion is favored when water becomes less limiting. Males increase reproductive success through contact with many females, which can often be achieved through greater mobility. In most monogamous mammals, both males and females disperse (Dobson 1982). In Georgia, sexual competition among male white-tailed deer (*Odocoileus virginianus*) appeared to be the primary stimulus for dispersal (Kammermeyer and Marchinton 1976). Most dispersers were young subordinate bucks of breeding age. Nelson and Mech (1999) suggested the recent range expansion and establishment of new wintering areas of White-tailed deer in North America resulted from dispersal of yearlings. Male dispersal occurs in species that live in permanent herds, such as impala (*Aepyceros melampus*; Murray 1982), or African buffalo (*Synerus caffer*; Sinclair 1977). Sinclair (1977) found an increasing tendency for male buffalo to depart from mixed herds as they grew older, and those greater than ten years were permanently displaced by dominant breeding bulls. According to Prins (1989), rutting activities in mixed herds diminished a male's physical condition, while males in bachelor herds improved their condition. Distant movements of male muskoxen (*Ovibos moschatus*) on the Seward Peninsula probably improved their prospects for breeding whenever social competition was intense (Smith 1989). In monogamous and

territorial species such as dikdik (*Madoqua rhynchtragus*) and Roe deer (*Capreolus capreolus*), all offspring of both sexes disperse to find mates (Bobek 1977). Also, both sexes (although mostly males) disperse in species with loose social organization, such as Black-tailed deer (*Odocoileus hemionus columbianus*; Bunnell and Harestad 1983). Conversely, female Uganda waterbuck (*Kobus ellipsiprymus*) are the most active in dispersal, searching new areas for awaiting males (Spinage 1982). Female dispersal has been observed in Red deer (Clutton-Brock and Albon 1985) and Roe deer (Bobek 1977). An increase in population density stimulates dispersal of White-tailed deer bucks (Nelson and Mech 1984), but not females (Nixon et al. 1991, Nelson and Mech 1992). Social organization of a species influences dispersal rates (Baker 1978). In ungulates that occur in moderate sized herds, such as elk (*Cervus elaphus*), females disperse in small groups, splitting off from the group and establishing an adjacent home range. Wildebeest typically occur in large herds and may disperse in large groups (Sinclair 1992).

DOES THIS WORK FOR HUNTER-GATHERERS?

These biological classifications for movement do not differ much when compared to anthropological discussions of human mobility (**Table 1.1**). Anthropologists (Murdock 1967; Varien 1999) often classify human movement in terms of fully nomadic (comparable to dispersal), semi-nomadic (comparable to migratory), semi-sedentary (comparable to limited migration), and household or community movement (comparable to dispersion and convergence).

Table 1.1 Summary of the different types of movement and benefits to mobility.

Types of Mobility	
Animals	Humans
migration	semi-nomadic
dispersal	fully nomadic
limited migration	semi-sedentary
sedentary	fully sedentary
dispersion and convergence	household mobility/sedentism
Benefits (cultural/reproductive/survival) of Mobility	
Animals	Humans
ecological pressure	ecological pressure
finding mates	finding mates
disease	disease
predation	warfare
competition for resources	competition for resources
high quality food	high quality resources
thermal stress	thermal stress
insect harassment	insect/pest harassment
inbreeding avoidance	inbreeding avoidance
lack of group fidelity	lack of group fidelity
	<u>cultural transmission</u>
	hunting technique
	prey choice
	hunting technology
	social gathering
	procurement
	knowledge exchange
	trade

DEFINING HUMAN MOVEMENT

Human movement is often defined as a continuum with mobile and sedentary groups at opposite ends of the spectrum (Kelly 1992:44). In other words, highly mobile groups are those where residential mobility is frequent, whereas fully sedentary settlement systems are those in which at least part of the population remains in the same geographic location year round. Eder (1984), however, posits that mobility and

sedentism are not on either ends of a continuum. This statement is clear when one considers a circumstance by which residential place decreases and logistical mobility increases within a group (see Varien's (1999:11) example below). The mobility of residential location and individual mobility are two completely different movement strategies. While there appears to be some sort of mobility continuum, a definition of mobility may not be determined without considering the scale of movement.

Binford (1980) was one of the first researchers to define mobility in terms of both individual and group movement, but in this construct sedentism is observed as a group rather than individual characteristic (Varien 1999:10). For example, Varien (1999:11) points out that, in Binford's (1980) model, once group movement is fixed for the entire year they are defined as sedentary, and mobility is organized by individuals or task groups. Sedentary individuals who move supra-annually are unaccounted for by most definitions of mobility (see Varien 1999 for an exception).

Clearly, defining concepts of mobility is no simple task. A single meaning eludes us because anthropologists choose to examine human movement in a number of different ways. Those interested in examining more mobile individuals or groups define mobility in terms of how much or how little humans move individually or in groups seasonally or annually. When discussing less mobile or sedentary individuals or groups, one must define how one wants to examine the variability of movement within a complex settlement system. For example, some individuals may be quite mobile while their group or certain other individuals may only move once every five years. So, if the definition of mobility is highly dependent upon the topic of interest

(i.e., how frequently people move, how infrequently people move, or how people move in relation to their group or other individuals), how do these definitions affect how anthropologists model mobility?

Generally, models of mobility are constructed based on how modern humans structure their movement around their subsistence economy and environment (Binford 1978, 1980; Kelly 1983, 1992:46-48, 1995; see also Varien 1999:29). The primary subject of concern for these models is how often individuals and groups move. Touched on briefly above were the concepts of residential versus logistical mobility. To generalize, residential mobility is movements of the entire group from one camp to another, whereas logistical mobility is movements of a subset of the whole, generally task groups from a residential camp (Binford 1980). Using these classifications, Binford (1980) went on to describe hunter-gatherer settlement systems in relation to subsistence and environment. These systems categorized foragers and collectors where foragers are found in nonseasonal environments and generate residential bases and foraging locations and collectors are found in seasonal environments and create residential bases, locations, field camps, stations, and caches. These models have seemingly worked well for predicting hunter-gatherer movement at a group level (Berry 1982; Euler et al. 1979; Dean et al. 1985).

THE ADVANTAGES OF HUMAN MOBILITY

The advantages of movement are somewhat hidden in the discussion above. Why do humans move residentially and logistically? What could possibly be the root cause of

making optimal or biologically advantageous decisions regarding moves on an individual or group level? The answer, quite simply and perhaps obviously, is subsistence. It should come as no surprise that, as appeared in our discussions of dispersal, migration, limited migration, and dispersion and convergence, that species, first and foremost, make mobility decisions based on the location, availability, abundance, and regularity of food (and water). It follows that eating is an advantageous behavior benefitting reproduction and fitness.

The primary focus of this research is to determine how humans structure themselves in relation to the environment by defining the role bison movement plays in the structure of Folsom mobility. A behavioral ecological paradigm posits that “despite their possession of exceptional characteristics humans are not immune to ecological constraints” (Dunlap 1980:8), and that “adaptation to the environment plays a major (but by no means singular) role in conditioning the variability seen in hunter-gatherer societies” (Kelly 1995:35; see also Binford 1980, 1983; Jochim 1981; Smith and Winterhalder 1981). This approach allows aspects of modern hunter-gatherer behavior to serve as analogs to Paleoindian adaptations because living and ancient foragers operate under the same general structure of evolutionary principles. This is not to say that the first occupants of the western hemisphere are identical to modern hunter-gatherers, but understanding the relationships between environmental and cultural variables aids in reconstructing the past (Kelly 1996). Variables relevant to the structure of advantageous human mobility are of interest to this study.

A REVIEW OF PALEOINDIAN MOBILITY

Many of the current views of Paleoindian mobility stem from Kelly and Todd (1988). They envision late Pleistocene foragers engaged in a “system in which residential groups moved from kill to kill” (Kelly and Todd 1988:236) and would “begin an almost immediate search for further resources” following a kill event (Kelly and Todd 1988:238). Regular encounters with bison eliminated the need for intensive processing and result in frequent residential moves over long distances.

Folsom hunter-gatherers employed such residential moves and “may have been the most mobile pedestrian hunter-gatherers to inhabit the globe (Amick 1996:411).” This observation is based on lithic raw materials present in Paleoindian assemblages, and particularly those of Folsom, that have been transported over huge distances, not uncommonly exceeding 400 km (e.g. Amick 1994a, b, c, 1996; Hester and Grady 1977; Hofman 1999; Hofman et al. 1991). This pattern is especially well documented for Southern Plains Folsom sites, but evidence for the long distance transport of lithic raw materials is present in sites in the Northern Plains and Rocky Mountains as well (e.g. Frison 1982; 1984; Jodry 1999; MacDonald 1999; Root 2000; Waguespack et al. 2002). Folsom mobility is, then, seen as an adaptation to the hunting of bison among a highly mobile, gregarious species.

Amick (1994a, 1996, 2000) sees Folsom hunter-gatherers as mimicking the supposed east-west migrations of bison from the Southern Plains in the warm season to the sheltered basins of New Mexico in the cold season. Based on the regular occurrence of central Texas Edwards Plateau chert in Folsom sites in the New Mexico Basin and

Range, Amick believes Folsom peoples regularly “geared up on Edwards chert sources, then exploited the grasslands of the Southern Plains during summer and early fall and then moved on to winter in the intermontane Rio Grande Valley (Amick 1996:417).” He suggests that the total annual residential mobility of some Folsom groups in this region could have exceeded a distance of 1,400 km (Amick 1996:418). Using ratios of projectile points to preforms and ratios of point bases to tips compiled by region, Amick (1994a; 2000) further argues that Folsom hunters logistically exploited the Southern Plains and small basins and uplands of the Basin and Range, while frequent residential moves and limited logistical forays were used in the larger Tularosa, Albuquerque, and Northern Jornada del Muerto basins.

Hofman (1999) suggests a similar pattern of movement for Southern Plains Folsom groups to that of Amick (1994a, 1996, 2000), but instead argues for a redundant pattern of land use, independent of region: “Folsom technology was sufficiently conservative and efficiently organized to enable similar patterns of mobility and group movement throughout and across diverse terrains (Hofman 1999:403).” He further suggests that Amick’s data may be problematic due to the latter’s reliance on data from private collections, in which Folsom preforms are often underrepresented because they are not as readily identifiable as finished points (Hofman 1999:401). Folsom points from the Southern Plains were also used by Hofman (1994; 1999) whereby he noted consistent patterns of transport of lithic raw materials. In particular, Edwards chert, the raw material of choice for Southern Plains Folsom peoples, is most often transported to the north and northwest of the source area located in central Texas, up to a distance of 600 km. Alibates silicified dolomite from the panhandle of

Texas tends to have been moved north, northwest, and east, but notably it very rarely occurs in the form of Folsom points in central Texas (Hofman 1994).

Hofman (1999a:403-407) proposes that Southern Plains Folsom bands acquired Edwards Chert during the winter. In the cold season, he suggests that residential mobility was reduced while groups wintered in the Dissected Plains, off the high Llano Estacado, relying on “sheltered settings, diverse resources, and dispersed bison herds...” (Hofman 1999:405). Winter was a time for hunkering down and replenishing and repairing toolkits. He does not, however, believe that winter residential mobility would always have been restricted. Depending on the responses of bison to climate, Folsom groups may have utilized all areas of the Southern Plains during all seasons. During severe winters, however, Folsom groups and bison would have retreated to more sheltered settings (Hofman 1999:405-406; see also Greiser 1985). Support for this model is based on seasonality estimates for the bison kills at the Folsom, Lipscomb, Lake Theo, and Cooper sites, all late summer to early fall kills falling on the margins of the Southern High Plains (Hofman 1999:404).

Subsistence is often considered the driving force behind Paleoindian mobility for a number of reasons. Most notably is the long held inference that Folsom point users were bison hunting specialists (Cassells 1983:69; Collins 1999:30; Hofman 1992:198; Hofman and Todd 2001; Sellards 1952:149). The first Folsom sites were found because of the presence of bison bones in association with Folsom points (Meltzer 1993:293-294). In addition, Folsom sites are usually regarded as such when a Folsom point – a hunting tool – is found. The immediate assumption when Folsom sites were

initially examined was that bison hunting was of primary concern to the makers of Folsom points (e.g., Roberts 1936:37). Historically, bison were seasonally migratory on the Plains, and successful hunting required following herds (Epp 1988; Hofman and Ingbar 1988:346). The conclusion, therefore, was that Folsom point users were highly mobile bison hunters.

High mobility is commonly directly inferred from a curated tool design (Hofman 1991) and the direct procurement of non-local toolstone (e.g., Amick 1994:423, 1996:417-420; Hofman 1992:197; LeTourneau 2000) derived from sources ranging from 100 km to 900 km (Tankersley 1989:268-270). Based on ethnographic and archaeological research, when toolstone is scarce curation becomes necessary to maximize the efficient use of materials (Kelly 1988:719). For Folsom, high tool-to-debitage ratios and depleted tools reflect the maintenance and long use of tools (LeTourneau 2000:21). In addition, bifacial cores have been argued as the primary artifact, suggesting a curated Folsom lithic technology (e.g., Amick 1999:2; Bement 1999:149; Kelly and Todd 1988:237; Wyckoff 1999). Bifacial cores would have been useful for highly mobile people because they were portable, and one could continuously remove flakes from the core for both informal and formal tools (Goodyear 1989:3; Kelly 1988; Parry and Kelly 1988). LeTourneau (2000), however, argues that there is a lack of evidence to support a bifacial core technology during Folsom settlement, but he does agree that Folsom used a curated toolkit composed of a few small bifacial cores and flake blanks. Bamforth (1986:40) has noted (based on ethnographic and archaeological data), though, curation can be present under conditions of either high or low mobility.

Curating artifacts if widely accepted for Folsom behavior, as it is generally argued that reliance on trade would have been risky for highly mobile bison hunters (Hofman 1992:198). In addition, LeTourneau (2000:280) concludes that 66 percent of all Folsom artifacts are made of non-local toolstone, and exchange cannot explain the distribution. Thus, the movement of non-local toolstone from sources ranging from 100 km to 900 km (Tankersley 1989:268-270) is evidence of the long distance movement of Folsom people, and not contact between groups at that distance.

Tracking the movement of toolstone and the degree of rework/reuse has been at the forefront of Folsom mobility models (Amick 1996; Bement 1999; Ellis and Lothrop 1989; Hofman 1992; Holen 2001; see also Montet-White and Holen 1991). These studies often use distance-to-source interpretations, artifact curation, or retooling schedules to identify and interpret Paleoindian mobility. The general focus of these investigations is to identify the direction, scale, and frequency of human movement.

Hofman (1991) for example, discusses the distance from sources of Edwards chert and projectile point rejuvenation relative to Folsom mobility. He concludes that a weak negative relationship exists between the percentage of Edwards chert Folsom points and increasing distance from source, and a strong positive relationship between the percentage of reworked Folsom points made of Edwards and distance from source. In addition, Hofman examines the percentage and distance from source of multiple lithic types used for projectile point manufacture at southern Plains Folsom sites. He suggests Folsom movement was east-to-west and west-to-east between the Llano Estacado and lower Rolling Plains. Movement on the Llano Estacado is

suggested to have occurred from south-to-north. While Hofman's (1991) model addresses the direction of human movement to some degree, it alone cannot accurately account for variation that occurs during the use of a Folsom point due to interaction with the environment (Hofman 1992), or determine the direction of seasonal movements (Bement 1999).

Although the movement of toolstone indicates the possible range of Folsom mobility, the distribution of lithic material alone cannot explain why people would move such long distances when they could occupy areas at or adjacent to those lithic sources that were seemingly very important. Kelly and Todd (1988:235) suggest Paleoindians "made use of the landscape in a short-term and redundant fashion" due to "regionally abundant, but locally unpredictable, game animals coupled with a low density of hunter-gatherer groups." Following this model, then, Folsom hunters would have had to balance their need for toolstone with the seasonal and geographic availability of terrestrial fauna. Because bison were a resource used by Folsom hunters, the decision to move away from a lithic source must have been, in part, due to the availability and location of bison. Other resources or predetermined aggregation locales may also have motivated Folsom hunter-gatherers to move hundreds of kilometers away from a lithic quarry, but the role bison played in shaping such movements is of specific interest here.

A KNOW BISON MODEL NOT A NO BISON MODEL

Folsom hunters used numerous subsistence resources in the past, all contributing some degree to the mobility decisions made. Recent studies of Paleoindian economies have emphasized a generalized subsistence (see Bamforth 1991; Grayson 1988; Meltzer 1993). These discussions are supported by the realization of site recognition, sampling, and preservation biases, as well as arguments indicating the human tolerance of protein is limited (Hofman and Todd 2001:200-201). In addition, Bement (2003) posits that large bison kills with limited butchery and associated ritual during the late summer or early fall is evidence for aggregation, but not total dependence on bison by Folsom groups. Bement's argument implies that a predetermined location was selected, and multiple groups joined to conduct social activities. Consequently, because bison are mobile and unpredictable to exact location (Bamforth 1988; Epp 1988), long distance movement may occur primarily for social reasons.

Bison have been a key resource on the Plains from the late Pleistocene until historic times (Bement and Buehler 1997; Frison 1991). Humans cannot live on meat alone (Speth and Spielmann 1983), but bison can provide enough fat, fluids, vitamins, and technological materials to live for several seasons on a combination of meat, fat, marrow, blood, and rumen content (Todd 1991). So, while specialized hunting may be a rare form of subsistence (e.g., Kornfeld 1996; Meltzer 1993; Pianka 1983:266), it is not entirely out of the question. Is there evidence, though, that specialization did in fact occur during early Paleoindian occupation?

Specialization may be defined as an economy that is “based on the variety and intensity of species used” (Hofman and Todd 2001:201). Amick (1994) reviews the evidence for early Paleoindian subsistence and concludes that while the diet was much broader than previously thought, bison was probably the most used economic resource. Because bison hunters must be adequately prepared, trained, knowledgeable of bison behavior, and technologically capable, they cannot successfully hunt on a whim (Frison 1974, 1987, 2004). Further, knowledge of the location and timing of bison movement, as well as group cooperation becomes even more important during seasons when bison are hunted in large numbers (Hofman and Todd 2001:204).

Determining seasonality is reliant on finding plant and animal remains that, by proxy, provide seasonality. The season of kill is obtained by determining the age at death of the young animals at the site and relating that age to the calving season. The age is determined by a method describing the tooth-eruption sequence and wear pattern derived from modern bison (Reher and Frison 1980; Todd 1991). This technique is generally accurate to a two-month period (Bement 2003). Once the age is determined, it is related to the calving season to obtain the season of death. In the Southern Plains, the bison calving season generally occurs in April (Bement 2003). The season of death is determined by adding the age at death in months to the calving month. An animal determined to be 0.3 years (4 months) old at the time of death would have died in August or September (April plus 4 months).

The numerous large early Paleoindian kills on the southern Plains (see Bement 2003:30) indicate that during the late summer/early fall considerable effort was

invested in hunting bison. While early Paleoindian hunters may have had a generalized economy for some part of the year, archaeological evidence points toward a specialization focused on bison hunting during at least one season. Thus, Paleoindian mobility during at least one season of the year can be attributed to bison herd dynamics. Identifying the geographic location of bison throughout the year, then, becomes important in identifying human settlement on an annual scale.

Based on the foregoing discussion the following problem statement is generated: Assuming Folsom peoples were at least seasonally specialized bison hunters, detailed study of bison behavior and placement will shed light on Folsom mobility and subsistence structure. In this study, kill sites are used because they place people at points on the landscape at particular seasons of the year. The season is determined by the tooth eruption and wear sequence. Only people using Alibates and Edwards chert are considered in an attempt to narrow the number of players. Finally, the elemental analysis results of the bison teeth, and the spatial implications of the element analysis will be used to define patterns of bison/bison hunter organization, timing, and movement on the southern Plains.

ORGANIZATION OF THE STUDY

The following three chapters deal with the relevant Late Pleistocene/Early Holocene environmental proxy data, the techniques for examining where bison traversed at that time, and its application. Chapter 2 provides a paleoenvironmental and cultural historical background to the study. I define the spatial and temporal ranges of Folsom

on the Southern Plains and identify trends in technology, subsistence, and mobility leading up to and during the Folsom Period. In Chapter 3, I give a discussion of the pilot studies used to formulate the current study and provide the methodology for the current study. Chapter 4 presents the analytical results for the trace element analysis on bison tooth enamel using laser ablation techniques.

A case study is presented in Chapter 5 that incorporates the site specific data from known Folsom-age archaeological sites with the location and behavior of bison herds based on the trace element data. The discussion presents the results of the analysis and a model for Folsom mobility. Chapter 6 concludes the discussion.

CHAPTER 2: CLIMATE, GRASSES, BISON, AND HUMANS ON THE U.S. SOUTHERN GREAT PLAINS DURING THE EARLY PALEOINDIAN OCCUPATION (11,900 – 10,200 B.P.)

This chapter evaluates the impact that changing climate, vegetation, and fauna between 11,900 B.P. and 10,200 B.P. ultimately had on human adaptive strategies on the Southern Plains at the onset of the Folsom Period (10,800 B.P.). Climatic conditions are suggested to have shifted from cool and moist to colder and drier around 11,000 B.P. (Haynes 1993 226-232; Holliday 1997:2-4). Vegetation is thought to have shifted from a diverse flora consisting of numerous arboreal and some grass species to a homogenous steppe environment at 11,000 B.P., followed by the expansion of the grassland by around 10,000 B.P. Many terrestrial faunal species between 11,900 B.P. and 10,200 B.P. went extinct (Martin and Klein 1984), homogenizing the Southern Plains. I hypothesize that human adaptive strategies on the Southern Plains shifted from a moderately specialized approach to highly specialized around 11,000 B.P. There is a clear relationship between environmental change and human adaptation on the Southern Plains between 11,900 B.P. and 10,200 B.P. This relationship is the central focus of the current study.

The end of the Wisconsin Glacial Maximum (18,000 B.P.) saw a warming trend and rapid deglaciation in many parts of the world. The environmental conditions leading up to and including the Younger Dryas (YD) climatic event (11,900 – 11,000 B.P.) were highly variable, permitting the extinction of 33 genera of mammals (Martin and Klein 1984), and the complete colonization of the New World (Guthrie 1984).

Between 11,000 B.P. and 10,200 B.P. the YD brought with it a return to colder conditions. The effects of the gradual warming at the end of the Wisconsin Glacial Maximum, followed by the abrupt onset of the YD, had on the temperature, precipitation, flora, fauna, and human adaptive strategies on the Southern Plains is discussed below.

PROXY DATA

Sites on the Southern Plains from which data could be acquired are presented in **Figure 2.1**. The sedimentologic, pollen, and isotope data derived from each of these sites is discussed in detail below.

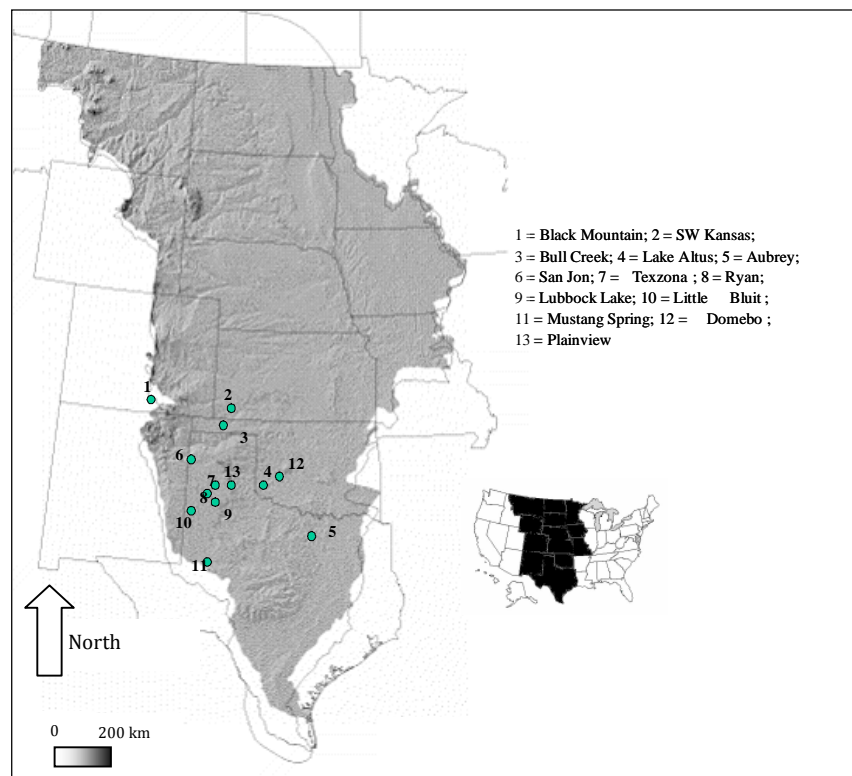

Figure 2.1 Southern Great Plains archaeological sites discussed in Chapter 2.

SEDIMENTOLOGY

Depositional history data of the Southern Plains has largely been derived from the Llano Estacado in the Texas Panhandle. Draws and sand dunes have received the most attention and have provided evidence of environmental change during the latest Pleistocene and early Holocene (Holliday 2000:2). Late Quaternary fill in the draws (after 12,000 B.P.) indicate a shift from flowing water to standing water and then the accumulation of eolian sediment (**Figure 2.2**; Holliday 1995:29-45,1997:52). The contact between alluvial and lacustrine sedimentation is well dated for the Southern Plains at around 11,000 B.P. and was followed quickly by palustrine conditions between 10,500 and 9,000 B.P. (Haynes 1993 226-232; Holliday 1997:2-4). Identifying moisture regimes during the late Pleistocene and early Holocene are the primary focus of research in the draws.

More recently, extensive investigations at Bull Creek (Bement and Carter 2005; Carter and Bement 2004) have provided environmental data along the High Plains – Great Plains Border (Bement et al. 2007). The deposits at Bull Creek mirror trends observed for the Llano Estacado. Short-term deposits of wind-blown silts, indicating a brief drying episode, are known to have accumulated no later than 11,070 B.P., just before returning to alluvial/colluvial deposition of sands, indicating a wetter period by 10,850 B.P. (Bement et al. 2007:42). By 10,400 B.P. stable soils had formed at the Bull Creek site (Bement et al. 2007:42).

Holliday (1997:12) describes the lunettes on the Southern High Plains as localized accumulations of eolian sediment deflated from playas in the Late Pleistocene. These lunettes are located on the northeast, east, and southeast sides of playas. Dunes have also been examined to describe the amounts of late Quaternary precipitation because dune activity is generally associated with drier conditions. Early Holocene-aged dune fields formed on the High Plains and likely originated from the Pecos Valley, west and northwest of the Llano Estacado (Holliday 1997:12). The orientation and sedimentation of lunettes and dunes on the Southern High Plains indicate a multidirectional wind pattern, with lunettes forming during the winter when playas are dry, and dune fields reflecting dominant northwest-to-southeast winds of the earliest Holocene (Carlisle and Marrs 1982).

Figure 2.2 Generalized stratigraphic profile of the Southern Plains draws (from Holliday 1995:14).

POLLEN

Pollen data for the Southern Plains is derived from Bull Creek (Oklahoma), Black Mountain (Colorado), and Domebo (Oklahoma) (**Table 2.1**). Pollen records from the Bull Creek locality in the Oklahoma panhandle indicate a change from a landscape supporting an open mesic sage scrubland mixed with hardwoods and an understory of mixed grasses and shrubs prior to 11,000 B.P., to one containing more oaks and grassy meadows (Bement et al. 2007:48). By 10,850 B.P., open grasslands dominate the landscape at the Bull Creek locality (Bement et al. 2007:48). Arboreal pollen from the Black Mountain site in south-central Colorado increases from 32 percent to 45 percent between 11,600 B.P. and 11,000 B.P. After 11,000 B.P. total arboreal pollen percentages decline from 45 percent to 30 percent (Jodry 1999:31). At this time grass pollen (*Poaceae*) increases slightly from 5 percent to 10 percent. Limited pollen data from the Domebo site indicates a shift in the grassland composition from 44 percent *Poaceae* at 11,045 B.P. to 66 percent at 10,123 B.P. (Leonhardy 1966:47). *Poaceae* is likely overrepresented in the Domebo sample, but the data seemingly indicates a shift in the vegetation composition of the locality over time.

Table 2.1 Pollen percentages from Southern Plains localities.

Bull Creek	¹⁴ C yr B.P.	Poaceae	Arboreal	Cheno-Am	Artemisia
	7,660	5%	5%	40%	15%

	11,045	44%	?	5%	?

ISOTOPES

Isotope data for this study is derived from numerous sites on the Southern Plains, and are determined from organic carbon (**Table 2.2**). Carbon isotope ratios from Bull Creek, southwest Kansas, and Lake Altus indicate an abrupt shift to cooler (-8°C) temperatures at 11,000 B.P. followed by a continued warming trend (Bement et al. 2007:44). Isotopes from Black Mountain (Jodry 1999:28), Plainview (Holliday 1995:56), and Southern High Plains lunettes and playas (Holliday 2000:4) are also lower prior to 11,000 B.P. and higher after 11,000 B.P. Isotope signatures from Aubrey (Humphrey and Ferring 1994:205), Mustang Springs, and Lubbock Lake Landfill (Holliday 1997:80 Figure 5.3), however, are higher before 11,000 B.P. and lower after 11,000 B.P.

PRE-YOUNGER DRYAS

Climate change between 11,900 B.P. and 10,200 B.P. clearly restructured vegetation communities on the Southern Plains. A review of the data presented above indicates that an abrupt switch from moist to dry conditions occurred around 11,000 B.P. based on pedology. In addition, dune orientation and deposition reflect dominate northwest winds throughout the Pleistocene/Holocene transition with strong winter southerly and easterly winds when lunettes are accreting.

GRASSLANDS

Limited pollen data indicate a dominant presence of arboreal pollen with some grass pollen prior to 11,000 B.P., and Poaceae pollen dominance on the Southern Plains by around 10,500 B.P. Stable carbon isotopes show relative stability between 11,900 and the onset of the YD followed by an increase around 10,500 B.P.

The pre-YD climate on the Southern Plains has long been described as cool and moist (Graham 1987; Sellards 1952:152). Southern Plains sedimentology, to date, indicates higher annual precipitation before and lower precipitation after 11,000 B.P. The stratigraphic abruptness described by Haynes (1984:345) and Holliday (1997:2-4) at 11,000 B.P. indicates a significant climate change whereby pre-YD precipitation was much higher than that of the YD.

Dune field orientation and deposition corroborate this evidence. During the Late Pleistocene northwest winds were accompanied by southerly and easterly winds causing a cool (more so than present), moist climate with less seasonal variation. Lunettes during this time were likely stable (Holliday 1985), indicating the presence of playa water year-round. The insolation increase on the Southern Plains during warmer months between 11,900 B.P. and 11,000 B.P. was seemingly accompanied by strong northwest (or weaker southeast) winds causing cool summers (**Figure 2.3**). During the winter, weaker northwest (or stronger southeast) winds dominate and produce storm track precipitation (see also Kutzbach and Webb 1993:9) keeping the draws and playas wet (**Figure 2.4**).

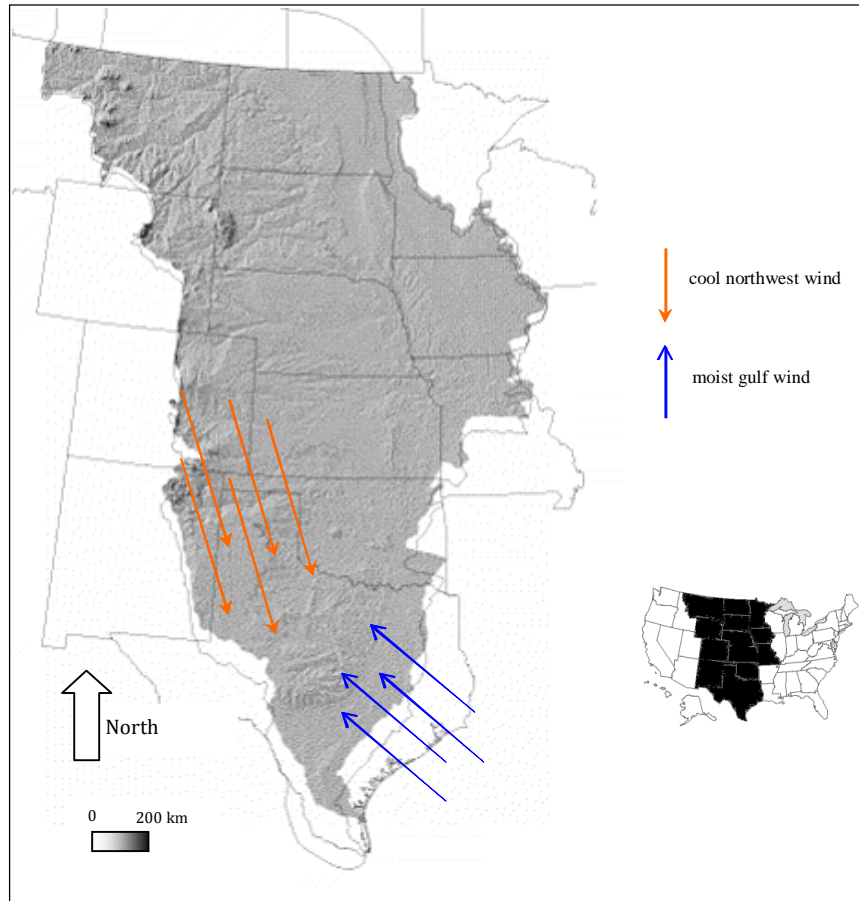

Figure 2.3 Generalized summer wind patterns on the Southern Plains between 11,900 and 11,000 B.P.

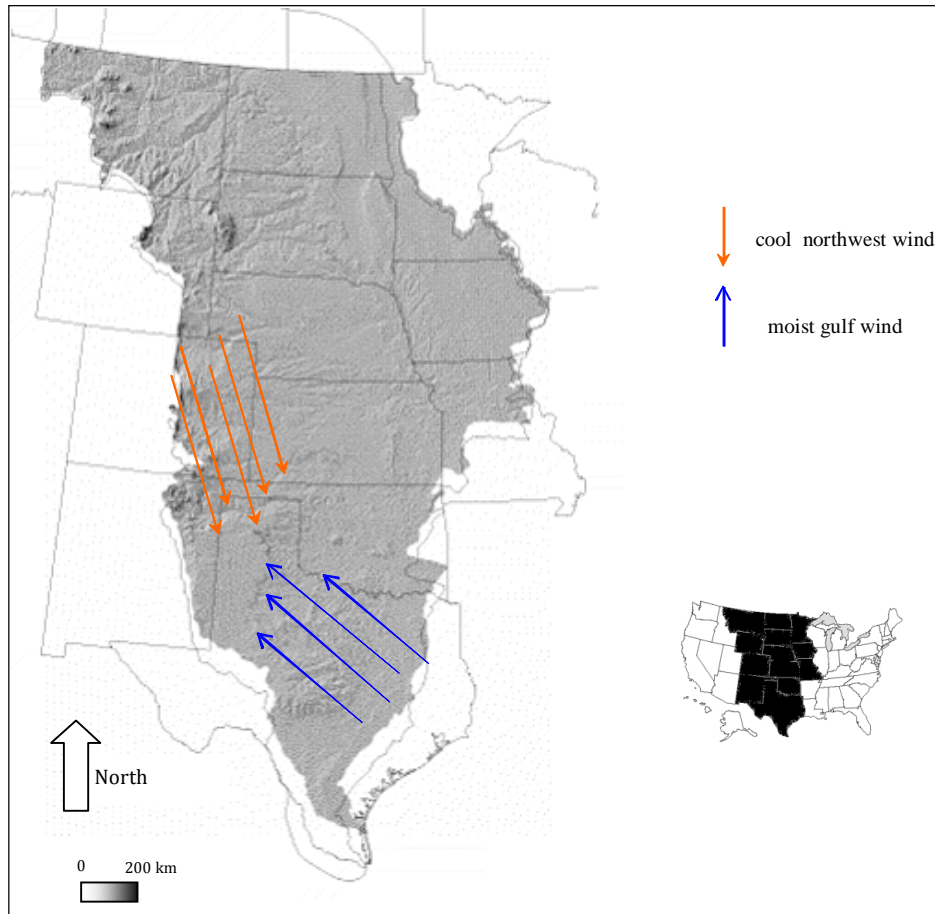

Figure 2.4 Generalized winter wind patterns on the Southern Plains between 11,900 and 11,000 B.P.

In addition to cool, moist, and less seasonal climates, the vegetation between 11,900 B.P. and 11,000 B.P. was composed of higher percentages of arboreal species and a moderate amount of grassland cover on the Southern Plains. Further, stable carbon isotopes show a dominance of C3 plants and trees (plants = -22 to -24; trees -24 to -28) near lakes, and a mix of C3 and C4 (-9 to -17) plants during this time. The data correspond to the climatic reconstruction presented above because C3 species have been shown to thrive under cool, moist conditions (see Epstein et al. 1997; Risser

1985; Tieszen et al. 1997), and prefer winter precipitation (Paruelo and Lauenroth 1996).

FAUNA

The temperature and precipitation regime of the pre-YD environment promoted greater diversity and a wider dispersal of vegetation patches and thus supported a diverse fauna (FAUNMAP Working Group 1996). However, between 11,900 and 10,200 B.P. numerous species went extinct, but the bison (and several Cervids) did not (**Figure 2.5**). The longer growth season (as a result of cool, moist climates) before 11,000 B.P. favored higher diversity of plant, and therefore animal species. Most large herbivores made use of a broad range of habitats within a near homogenous landscape (Guthrie 1984:267). Bison during the Late Pleistocene were larger than extant bison (Frison 1991; McDonald 1981), and the herd size and range of bison presumably was not as extensive as later in time (FAUNMAP Working Group 1996). Less seasonality and more evenly distributed annual precipitation promoted short-lived C4 summer and winter forage. Winter precipitation encouraged the growth of C3 grasses that are important to providing enough nutrients to nursing cows in the spring (Peden et al. 1974:494). Bison herd populations were likely restricted due to small, but widely dispersed grassland regions (Chambers 1998).

Figure 2.5 Comparative percentages of extinct mammals by trophic class (data from Graham and Lundelius 1984:235).

POST-YOUNGER DRYAS (11,000 – 10,200 B.P.)

GRASSLANDS

The Post-YD period has long been described as a dry period accompanied by the extension of the grassland (see Borchert 1950:36). This assertion is supported by ongoing pedologic analyses. More recently, the YD event itself (11,000 B.P.) has been characterized as a brief return to glacial-age temperatures (Rooth 1982). Lunettes during the YD were accreting (Holliday 1995), and dune field activity indicate sustained northwest winds causing a cooler and drier annual climate (compared with the Late Pleistocene) on the Southern Plains (**Figure 2.6**).

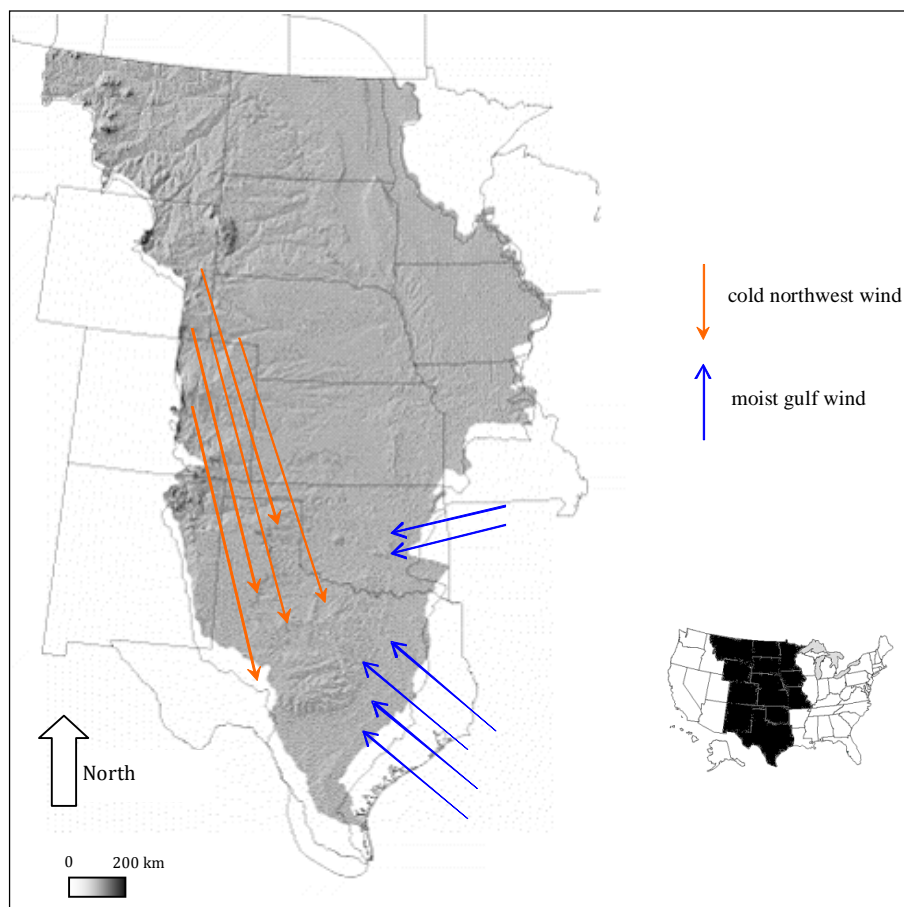

Figure 2.6 Generalized Younger Dryas wind patterns on the Southern Plains.

Pollen data for the Southern Plains during the YD event indicate a dramatic decrease in the percentage of arboreal pollen and an increase of grass pollen (see also Axelrod 1985:181). Under cold and dry conditions, the data presented here show that many C3 trees were unable to compete with the C3 and C4 species creating a steppe environment composed of grasses, composites, chenopods, and some woody plants (Bement et al. 2007; Guthrie 1984:266; Jodry 1999:31). Some playa sites observed in this study do not indicate an increase in carbon isotope ratios, signifying little change in vegetation. Presumably, the Aubrey and Mustang Spring locales remained wet

year-round during the YD. Overall, though, floral species diversity was decreased (primarily a decrease of many mesic species) as a result of decreased precipitation (Axelrod 1985:181) and shorter growth seasons (Guthrie 1984:282) on the Southern Plains following the YD.

FAUNA

Drying after the YD event encouraged the expansion of the grassland community and homogeneity in flora and terrestrial fauna on the Southern Plains. The warming and drying trend after the YD no doubt had lasting effects on bison herds that had adapted to the grasslands during the Late Pleistocene. The expansion of herds was likely due to bison occupying a number of ecological niches opened after the full extinction of other herbivore species (Graham and Lundelius 1984), as well as the homogenous expansion of grasslands across the Great Plains (Chambers 1998). In addition, seasonal food availability in different locations may have led to a more structured movement of bison herds (Bement 1999). Bamforth (1988) and Epp (1988) suggest modern bison are seasonally predictable in range location, but unpredictable in exact location. Similarly structured bison migration and wandering is suggested to have occurred in the past (see Chisolm et al. 1986), and paleontological archaeological data indicate that bison grazed in specific regions (FAUNMAP Working Group 1996).

Extinctions continued following the YD event and it was at this time that bison populations increased compared to that of other terrestrial species. After 11,000 B.P., the increased summer solar radiation and the winter arctic fronts amplified seasonal

temperatures (Broecker et al. 1988). Increased seasonality coupled with decreased precipitation caused a shift to shorter growing seasons and greater biotic zonation. The Post-YD climate favored *Bison antiquus* over a number of large herbivores that went extinct for reasons discussed below:

- 1) Bison are better adapted to grazing a specific habitat and less selectively graze the dominant grasses on a landscape (Hartnett et al. 1997:79; Knapp et al. 1999:41; Peden et al. 1974:495; Reynolds et al. 1982:986) than other herbivores. The cold, dry climate of the YD decreased floral diversity creating a steppe environment that was lacking the nutrients needed to carry a diverse fauna. Bison's four-chamber digestive track is adapted to rendering nutrients from low grade graze.
- 2) Bison have shorter gestation periods and higher protein milk than the herbivores that went extinct. Guthrie (1984:283) proposes that herbivores having gestation periods greater than nine months and milk protein less than 4 percent went extinct. These two factors are used to describe conservative ungulate life strategies. More conservative life histories (gestation > 9 months, milk protein < 4 percent) do not do well in short growing seasons because of their "inability to capitalize on a short nutrient flush" (Guthrie 1984:283). The less conservative strategy employed by bison allowed the species to take advantage of seasonal abundances of

vegetation rather than requiring high quality forage throughout the year.

Whether or not these are the two driving factors for the success of bison during the YD, the fossil record indicates the extinction of many herbivores and the increase in bison population on the Southern Plains (FAUNMAP Working Group 1996). Biological and behavioral adaptive strategies likely contributed to bison survival. The increase in bison population on the Southern Plains no doubt had lasting effects on the smaller fauna, as well as predators still present in the region.

SOUTHERN PLAINS FOLSOM SUBSISTENCE

As a predator, Early Holocene hunter-gatherers presumably had a generalized terrestrial fauna-based hunting strategy throughout the period between 11,900 and 10,200 B.P. (Kelly and Todd 1988). Oftentimes, these early hunter-gatherers are termed big-game hunting specialists (see Amick 1994; Waguespack and Surovell 2003). Archaeological evidence supports this assertion on the Southern Plains. Mammoth, horse, camel, and bison are all known to have been frequently procured on the Southern Plains (e.g., Johnson 1991:222). Highly specialized hunting would involve the acquisition of a single species, while less specialized procurement focus on a variety of resources. The following paragraphs will describe the adaptive strategies made by humans before and after 11,000 B.P. as a result of changing climate, flora, and fauna.

One may only assume that predators would have a number of animal species to prey upon, based on the evidence presented earlier (that cool, moist climates supported diverse flora and fauna),. The human predators between 11,900 B.P. and 11,000 B.P. on the Southern Plains seemingly favored several large herbivores. The stone tool technology and faunal procurement strategies attest to a moderate degree of efficiency, if not specialization, by these individuals.

Pre-YD peoples (Clovis) employed a stone tool technology composed of high quality raw material, cores, blades, bifaces, and caches (Collins 1999). The distribution of raw material during this time across the Southern Plains suggests high mobility (Holen 2001). However, caches seem to indicate more predictable subsistence rounds whereby groups would return to an area and collect stored blades and bifaces (Collins 1999:30). Collins (1999:14) has also described the Clovis tool kit as utilitarian. Comparatively, the pre-YD tool kit was more extensive and probably limited mobility more so than during the YD. Add other tools such as bone and ivory, and one has even more to carry.

Faunal procurement on the Southern Plains usually was diverse pre-YD, when kill and campsites are composed of several species of large herbivores, mammoth generally having the highest NISP and MNI (Agenbroad 1984). In addition to mammoth, humans are known to have hunted horse, camel, giant bear, giant armadillo, and bison on the Southern Plains (Johnson 1991:222). Small mammals are rarely discovered and aquatic species are absent from Clovis assemblages further suggesting a moderately specialized subsistence.

The data presented in this chapter characterizes the YD as a period of decreased temperatures and precipitation. The climate favored competitive C3 and C4 species, and hurt mesic tree populations on the Southern Plains. Bison (and some Cervids) were able to survive the abrupt climate and floral change due to biological and behavioral characteristics not found in many Late Pleistocene grazers and browsers that went extinct. During the YD, human groups on the Southern Plains had the choice of either migrating to adjacent areas with more diverse flora and fauna, or staying on the Plains and intensifying use of the fewer available resources. Based on the stone tool technology and subsistence practices on the Southern Plains during the YD, it appears that some groups stayed and intensified.

YD peoples (Folsom) on the Southern Plains used high quality raw material, like their predecessors, to make tools. The tool kit changed, however, consisting of versatile bifacial cores and highly specialized dart points (Collins 1999; Wyckoff 1999). Such technology is thought to have encouraged high mobility and allowed unpredictable treks across the landscape. In addition, Folsom dart points during the YD, unless lost, could be easily rejuvenated and used multiple times.

Most Folsom sites on the Southern Plains are kill locations. The YD period on the Southern Plains is the first time in the New World that we begin to observe the specific targeting of large herds of animals. Prehistoric bison procurement developed within a context of short grass prairie ecology, bison demographics, and human technological and subsistence organization (Bamforth 1985; Binford 1980; Bonnischsen et al. 1987; Cassells 1983; Collins 1999; Hofman 1991, 1992; Hofman

and Todd 2001; Holen 2001; Hughes 1977; Johnson 1987; Kelly 1983; Kelly and Todd 1988; Reher and Frison 1980; Roberts 1936; Sellards 1952). Bison kill sites are a common site type on the Great Plains of North America (Dibble and Lorrain 1968; Davis and Wilson 1978; Bement 1986, 1994, 1997, 1999; Bement and Buehler 1994, 1997; Speth 1983; Hill and Hofman 1997; Hofman et al. 1991; Frison 1970, 1974, 1987, 1991, 1996, 2004; Frison and Todd 1987; Johnson 1997; Reeves 1978; Stanford 1978, 1984; Todd 1987a; Verbicky-Todd 1984; Wheat 1967, 1972, 1978). Reasons for conducting these kills include 1) the acquisition of a storable food source to supplement periods of perceived food shortages, such as overwintering; 2) the quick procurement of a sufficient food supply to meet the needs of a large, short-term aggregation of people such as seen at multiple band aggregations for ceremonial or social purposes (Bement 1999; Fawcett 1987; Verbicky-Todd 1984; and 3) to take advantage of a highly mobile food resource as it is available during herd migration through an area (Driver 1990). These various reasons are not necessarily mutually exclusive.

The processing of bison kills varies according to transport and subsistence decisions in answering basic questions such as: is the meat meant for immediate consumption or to be processed for storage; are the animal products to be transported long distances to the habitation site, or are the people going to move their camp to the area of the kill (Binford 1978, 1980); and, is a processing camp necessary before the products are transported to the habitation site? Models have been proposed that deal with ancient hunter-gatherer mobility strategies, settlement patterns, and non-bison resource exploitation. Among these are Kelly and Todd's (1988) model of

Paleoindian mobility strategy, Hofman's (1990, 1991, 1992, 1999) proposed Folsom mobility as reconstructed by lithic sourcing, and Bamforth's (1985) subsistence model on small kills (see Chapter 1 for descriptions of each). Following the steps of the earliest cultural ecologists many of these models examine subsistence technology in an effort to understand mobility, and therefore how humans organize themselves in relation to the environment. A better approach may be to first understand how the environment is structured.

CONCLUSIONS

Clovis and Folsom subsistence is generally based on a behavioral ecological construct that assumes the environment plays a large role in conditioning past and present hunter-gatherers. As evidenced by paleoecological and archaeological data, the environment between 11,900 B.P. and 10,200 B.P. encouraged Clovis on the Southern Plains to move frequently but predictably, and hunt a number of large terrestrial species of animals. Folsom on the Southern Plains while able to retain high mobility and a big-game focus, were forced to move more erratically, and hunt one of the only large herbivores left in the region as a result of the YD climate. These inferences are by no means an attempt at explaining all of the characteristics of the Clovis and Folsom "cultural complexes." Latitudinal, longitudinal, and elevation differences no doubt alter the adaptive strategies of Clovis and Folsom groups. The inferences made from one geographic region should not be expected to be the same in areas where climate, vegetation, and fauna are different, even if the variation is seemingly minor.

This chapter has identified the current thinking regarding adaptive strategies based entirely upon environmental change. Alternative or supplementary explanations certainly exist for Early Holocene culture change that go unforeseen today by the archaeologist. The concurrence of climatic, floral, faunal, and human alteration at 11,000 B.P., however, is not likely a simple coincidence. Furthermore, I am not proposing a large-scale restructuring of human subsistence strategies on the Southern Plains at the onset of the YD climatic event. Clovis and Folsom peoples on the Southern Plains were both highly mobile hunters of large terrestrial fauna. The YD event simply decreased the amounts and kinds of terrestrial fauna available to hunters possibly requiring Folsom to more intensively specialize on the remaining species.

The archaeological record presents bison as a prime candidate for this study because human adaptive strategies on the Southern Plains shifted from a moderately specialized approach to highly specialized bison hunting around 11,000 B.P. The following chapter describes a technique of extracting dietary data from bison tooth enamel to understand the relationships between bison movement and Folsom strategies for harvesting bison.

CHAPTER 3: THE ISOTOPIC AND ELEMENTAL ARCHAEOLOGICAL RECORD: PILOT STUDIES AND METHODS FOR GETTING THERE

Isotopic research indicates that intra-tooth sequential sampling is an effective method for reconstructing the dietary history of animals (Balasse 2002; Fricke and O’Niel 1996; Gadbury et al. 2000; Sharp and Cerling 1998; Wiedemann et al. 1999), and the composition of isotopes in skeletal remains can measure the geographic mobility of animals (Beard and Johnson 2000). Recent studies conducted at the University of Oklahoma and the University of Texas indicate that trace element analysis of teeth by electron beam and LA-ICP/MS methods also is appropriate for examining animal movement. These preliminary studies have shown that the dietary uptake of *Bison bison* and *Bison antiquus* may be directly related to the elemental concentration of the associated bedrock geology. Because modern bison are restricted residential herds, the isotopes and elements in modern bison teeth provide a map from which *Bison antiquus* herd movement may be reconstructed. Kill sites are nodes on the landscape where humans and bison interacted. Based on bison tooth eruption and wear schedules we can determine the season of such interactions. The toolstone used to make the projectile points found at kill sites identifies the region or territory of the hunters. The proposed study will reveal the dimension of hunting structure reflected in the use of migratory or resident bison herds to understand seasonal variability in human/bison interactions.

Bison, the target of the ancient hunters, provide the key to understanding the mobility and timing aspects of hunting groups on a seasonal scale. The examination of elemental compositions of soils, plants, and water across a region would require years of sample collection and testing and would cost several hundreds of thousands of dollars. This same information can be obtained by analyzing modern bison teeth from individuals raised in different areas of the Southern Plains. The widespread raising of bison over the last decade presents numerous samples from all regions. The teeth of modern bison provide a short cut in determining the differential distribution of trace elements around the Southern Plains. In much the way bison serve as proxies for establishing the seasonality of the kills through the study of the eruption and wear patterns on bison dentitions (Frison and Reher 1970), so too might these same dentitions provide the data to track bison movements across the plains. Mature bison tooth enamel is almost entirely composed of hydroxylapatite, a crystalline compound predominately of calcium and phosphate with the general formula: $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$. Enamel consists of isotopes and trace elements that are incorporated into the matrix during mineralization (Schneider and Blakeslee 1990). The trace element content in teeth and bone can be correlated with the trace element content of associated soils, plants, and water (**Figure 3.1**; Harper and Reed 1964). Because the enamel in this study is not remodeled once formed and not appreciably altered by diagenesis (Molleson 1988), the elemental composition reflects that of the diet, and by inference, the region inhabited during enamel mineralization.

Figure 3.1 The movement of trace elements through the biogeosphere. Minerals move from their geological source into soil, plants and animals and retain elemental concentrations and isotope ratios that reflect, but may not be exactly the same as, the source rocks. This provides a mechanism for linking bison to the region where they obtained their food.

The formation and mineralization of enamel (amelogenesis) is a complex process (Balasse 2002:156-157) that generally begins at the occlusal surface of the tooth and proceeds downward to the cementum-enamel junction (CEJ). This results in a down-tooth record of changing isotopic and elemental concentrations driven by dietary uptake (**Figure 3.2**). Most teeth in the bison dentary form prior to weaning. Only the mandibular fourth premolar (P4) and third molar (M3) undergo amelogenesis during

the third year of life (**Figure 3.3**). At this age, the elements for enamel production are obtained through ingestion of plants, soil on the plants, and water, rather than through the biofilter that produces mother's milk. These trace elements and stable isotopes reflect the compositions of the soil, grasses, and water where the bison grazed during the period of amelogenesis. Once initiated, enamel placement takes approximately 300 days and begins at the top of the tooth and progresses towards the root. Samples taken down the tooth at 5mm intervals would analyze enamel content at roughly 60 day (2 month) intervals. If distinct regions of the Plains contain specific suites of trace elements and grassland compositions, then analyzing the elements and isotopes in the tooth enamel would provide a geographical link. By comparing the elements in bison teeth obtained from kill sites with the geographical distribution of these elements, I will determine if the bison were resident and were killed in the area where amelogenesis occurred, or were migrant and were killed in an area different from that where amelogenesis occurred.

A hypothetical model may best describe how the proposed study will work. Three basic theoretical cells describe the proportional relationship between any two trace elements within a region. These are: element A occurs in greater amounts than element B; element A occurs in lesser amounts than element B; element A and B are equal. Additional relationships that modify the basic relationships include: The environment is depleted in both elements A and B or the area is enriched in both elements A and B. The regional diversity found in the soils, bedrock, water, and plant life indicate the Southern Plains contains subregions reflecting each of these element relationships. The hypothetical model describing the relationship of bison enamel

element and isotopic composition found at a kill site and the geographical distribution of those elements across the Southern Plains is provided in **Figure 3.4**.

Figure 3.2 Schematic diagram of enamel biomineralization. Note that at the formation stage (stage 3) enamel is only lightly mineralized. Full mineralization (expansion of crystallites) only occurs during the maturation stage (stage 5). Redrawn from Fincham et al. 1999.

Figure 3.3 Three year old bison mandible showing full enamel placement of an unerupted P4 premolar.

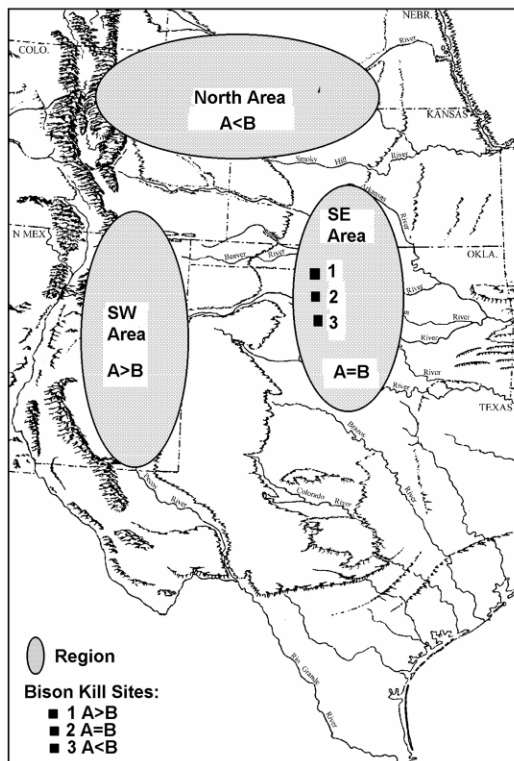

Figure 3.4 Hypothetical model of the distribution of two elements (A and B) in three regions of the Southern Plains and three bison kill site locations with different element compositions.

The hypothetical Kill Site 1 tooth analysis revealed the element relationship of $A > B$, indicating the bison was in the SW area during tooth enamel amelogenesis, and that it had moved into the SE area. Kill site 2 enamel contained equal amounts of elements A and B which is also the pattern in the area containing the kill site. Thus, site 2 contains local or resident animals. Site 3 enamel contained element A in lesser quantities than B and thus that animal had moved southward from the north area. Sampling of different layers on the tooth over the course of enamel amelogenesis provides a way to track the movement of bison across multiple regions. For example, if measurements are taken at increments down the tooth enamel and the results were: Increment 1 $A = B$, 2 $A < B$, 3 $A > B$, and 4 $A = B$, then this would indicate the animal had traversed the plains in counter-clockwise direction beginning and ending in the SE area during the period of enamel amelogenesis (approximately 1 year).

THE ELECTRON MICROBEAM PILOT STUDY

Following the hypothetical model, Graves, Bement and Morgan (2003) set out to determine the elemental composition of the P4 enamel by employing the electron microprobe. An advantage of the microprobe is that the tooth did not need to be divided into samples but instead strips of the enamel and root could be analyzed in increments from top to bottom. In 1998, microbeam analysis was performed on two modern bison teeth from Garden City, Kansas, two modern bison from Lawton, Oklahoma, and two ancient bison from the Cooper site, Oklahoma (**Figure 3.5**). Two mandibular P4 premolars were extracted from one individual from Kansas (K1-1, K1-2), and one mandibular P4 was taken from a second Kansas individual (K2), two

Lawton individuals (W1, W2), and two Cooper site bison (CM, CL). From each tooth a section of enamel approximately 0.5 cm in width was cut, using a Dremmel wafering saw, from the occlusal surface of the tooth down to the CEJ. The Kansas samples were placed in an epoxy, and the Oklahoma samples were embedded in thermoplastic. The difference in these mounting types is not known to alter quantitative chemical analyses.

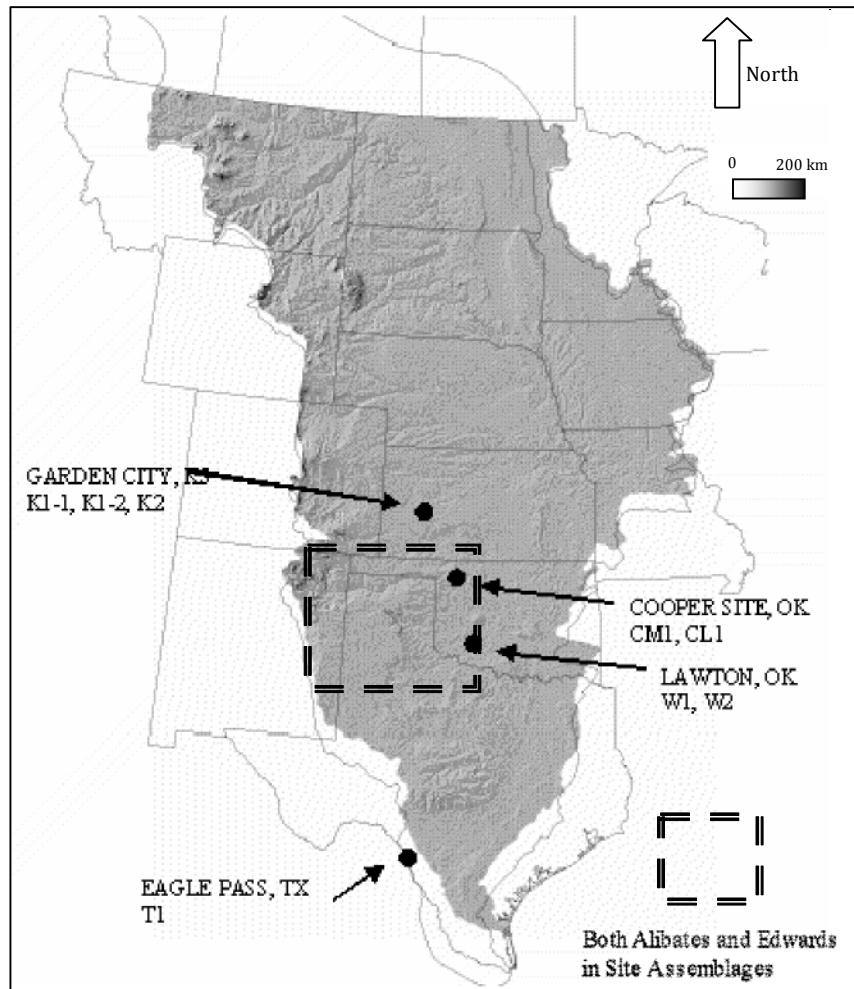

Figure 3.5 Locations of selected bison tooth samples used in the pilot studies.

During grinding and polishing, samples were examined under a binocular microscope to determine the quality of surface finish before proceeding to the next lapping stage. After polishing, the samples were made conductive by C-coating. All analyses were executed with a Cameca SX50 electron microprobe at the University of Oklahoma. Qualitative phase identification was accomplished by backscattered electron imaging coupled with Energy Dispersive X-ray Analysis using 20 kV acceleration voltage and 5 nA beam current. Images were acquired digitally into 1024 x 1024 pixel arrays. Electron Microprobe Analysis was performed by Wavelength-Dispersive Spectrometry (WDS) using first order x-ray emission lines. Intensity acquisition for all elements except Sr used a two-point linear background model; for Sr, a single point and slope model assuming a linear background was used. Elements that were examined (Sr, Pb, Ca, Mg, Mn, Fe, P, Se, Al) were analyzed using 20 kV acceleration, 20 nA sample current (measured at the Faraday cup), and a 20 μ m spot size. Oxygen was not analyzed directly but was calculated by stoichiometry on the basis of inferred/known cation charges for the elements. Selected elements have been shown to be effective in determining subsistence in bone and teeth (Schneider 1986) and were chosen because of their presence in enamel, their detectability, and their nutritional role. Testing points were selected every 0.5 mm from the CEJ to the occlusal surface for the Kansas samples, whereas points at 5 mm increments down the tooth were analyzed for the Oklahoma specimens. These results were then averaged and plotted against depth below the occlusal surface of the tooth. For the enamel, each 5mm increment is separated from the next by the time equivalent of amelogenesis of approximately two months.

Analytical totals derived from the study (avg. 91.3-91.6 wt. percent) were significantly less than 100 percent. Numerous factors may cause low analytical totals including: unaccounted for elements, low density/porosity, x-ray interference (overlap), valence problems, beam alteration of samples, dead time, or differences in background shape between the standard and unknown. As mentioned previously, no overlaps were determined. In addition, the only multivalent cations that may cause low analytical totals are Fe and Mn, but these are below detection level. An examination of counting statistics does indicate, however, that peak intensities are lower than 10,000 cps and significant differences are not observed in the backgrounds of the unknowns and standards.

With the elimination of the counting procedures above, the primary causes of low analytical totals for this study probably include the presence of light elements not analyzed for and low density/porosity. Among the light elements (C, H, F, Li, Be, B), only C and H are readily taken up by hydroxyapatites. Hydrogen is much too light an element to be analyzed by the microprobe. The samples were not baked during preparation and the organics had not entirely decomposed. Thus, the abundance of C likely contributed to lower analytical totals than expected in this study. In addition, the porosity of enamel may affect analytical totals. A void in the excitation volume results in low analytical totals (when more dense materials are used for the intensity calibrations). The apatite used as the Ca and P standard was a single crystal. Tooth enamel, however, does not represent a single crystal that is larger than the beam excitation volume, but is comprised of numerous prisms or rods that are composed of apatite crystals in varying sizes and shapes. So, the intergranular space between the

small crystals represents void space (and has other related surface effects such as x-ray scattering and diffraction) that will reduce the emitted x-ray intensity.

The results can be viewed at different scales. The most general level is the enamel as a whole where all down-tooth readings are averaged and provide a single assay for the entire tooth. At a finer scale, each series of readings at each of the 5 mm increments can be plotted against depth below occlusal surface and thereby provide a series of assays at points in the amelogenesis during the development of the tooth. The latter scale provides the opportunity to track changes in the inclusion of trace elements at different times of the year and thus potentially provide information on changing amounts of elements and their corresponding distribution in the grasses, soils, water, or all three. If the distribution of some of the elements incorporated during amelogenesis is found to be patchy with definite regional delineations, then the fine scale analysis may provide a means to identify how far and in what direction an animal moved during the season of P4 enamel development.

Quantitative analysis of the tooth enamel yielded results below the minimum levels of detection for most of the trace elements examined. Only Ca, P, Sr, and Mg could be detected by the methods used here. Because Ca and P make up most of the enamel structure, Sr and Mg are of interest for this study to identify diet. The results for the P4 premolars indicate that variations occur in Sr and Mg concentrations throughout the formation of the enamel (**Figure 3.6**). Presumably, the changes are a reflection of individual diets.

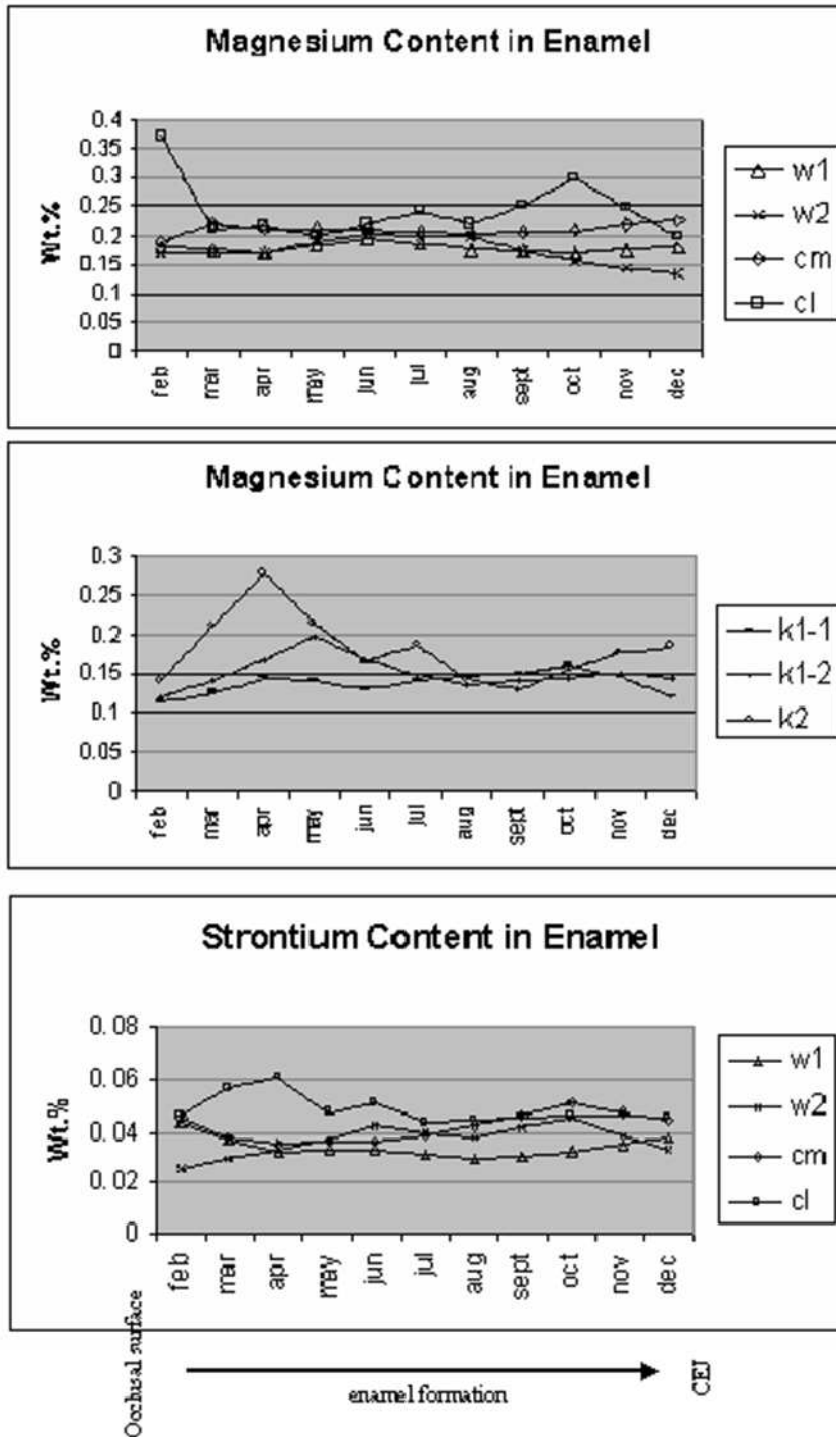

Figure 3.6 Results of the electron microprobe analysis indicating the Mg/Ca and Sr/Ca ratios in bison enamel. W1 and W2 are Wichita Wildlife refuge bison; CM is a Cooper middle kill and CL is a Cooper lower kill individual; K1-1, K1-2, and K2 represent two Kansas bison.

The analysis of bison teeth by microbeam methods is validated by this pilot study. The Kansas individual from which two mandibular dentitions were retrieved indicated remarkably similar down-tooth concentrations. However, a peak in Mg occurs in the K1-2 sample approximately 5-7.5 mm (April and May) that is not observed in K1-1. The discrepancy can be explained by a problem with the analysis of the testing points between 5 and 7.5 mm of the K1-1 premolar. The analytical totals (total weight percentages) for these points were significantly lower than totals for any other testing point (89 wt. percent versus 91-92 wt. percent). In addition, Ca and P were lower for the K1-1 premolar for the points between 5 and 7.5 mm. The missing Mg peak in the K1-1 signature is likely due to a problem with the beam focus during analysis resulting in low values for the elements. Thus, the concentrations for K1-1 between 5 and 7.5 mm should resemble the K1-2 content making the entire down-tooth record nearly identical.

The two Kansas individuals also exhibited similar Mg concentrations. Again, a large peak in the Mg concentration occurs early in the formation of the K2 enamel. Analytical totals for all of the testing points for the K2 specimen range from 90.613 to 92.498 wt. percent, so the Mg content likely reflects a variation in diet between the K1 and K2 individuals during the spring months. A complete dietary history for the Kansas bison is unknown, and the individuals could have been bought and sold to different ranches at different times during the formation of the enamel, causing elemental discrepancies. Any interpretation, however, is entirely speculation. The fact remains, though, that the elemental concentrations are alike throughout the majority of the K1-1, K1-2, and K2 enamel formation.

Overall, the Kansas specimens had lower concentrations of Mg than the modern and prehistoric samples from Oklahoma, and no Sr content. One factor that might explain the difference is the affect of the Dakota Aquifer in Kansas (Macfarlane 1996). The aquifer introduces high sodium bicarbonates and fluorine concentrations, causing the Mg and Sr content to be low in west central Kansas. There is, however, a significant increase of Mg in soils at the Kansas-Colorado border and a gradual increase towards Oklahoma (Macfarlane 1996). The dietary uptake of *Bison bison* from western Kansas and western Oklahoma resembles that of the associated soils.

Prehistoric trace elemental contents in soils have yet to be determined, but should resemble modern distributions. Magnesium and strontium concentrations within the prehistoric samples from Oklahoma are similar during the late summer/early fall (when herds would have been in the area based on the season of death for the Cooper bison) to modern bison from Oklahoma, and so, one may reconstruct bison movements based on modern distributions of trace elements. For the purposes of this pilot study, western Kansas may be defined as an area with lower Mg and Sr content, while western Oklahoma has higher levels of Mg and Sr.

There is some degree of variation in the elemental content of modern residential herds from Kansas and Oklahoma (StDev = 0.007-0.02 for Mg, 0.005 for Sr), but only the Kansas 2 (K2) and Cooper Lower (CL) samples exhibit a high degree of variation of Mg (StDev = 0.042 and 0.05). It may be inferred, then, that the Cooper Middle (CM) individual represents a residential herd. I will concentrate the remainder of this discussion on CL because the K2 individual could have been transported to a number

of locations during the time of enamel formation. After the initial formation of the P4 enamel, the CL individual moved into an area with lower Mg and higher Sr concentrations by April, while the other individuals had similar diets with lower Mg and Sr concentrations. By the early fall, CL moved into an area with similar Mg concentrations as encountered in the spring, but decreased Sr content. The CL individual then moved back into an area with similar Mg and Sr concentrations as when enamel mineralization began.

A plot of the Sr levels in the P4 enamel from the CL sample, the CM sample, two modern bison P4s from the western Oklahoma (Wichita Mountains Wildlife Area), and two modern individuals from Garden City, Kansas, shows variation in the amount of Sr incorporated in the enamel over the course of amelogenesis (approximately 1 year). The greatest difference is seen in the Sr level of the CL sample. The CL sample Sr is between one third and one half greater than that contained in any of the other Oklahoma samples at 5 and 10 mm below occlusal surface, suggesting that this animal grazed in an area with substantially greater amounts of Sr than was contained in any of the grazing areas covered by the other three animals during this stage of amelogenesis. The 15 and 20 mm below occlusal surface measurements indicate that the CL and CM individuals were in areas with comparable levels of Sr in the months just prior to their deaths in northwestern Oklahoma. The CM animal had Sr levels comparable to that of the modern Wichita Mountains Wildlife Area animals for most of the period of amelogenesis, suggesting the Middle Kill Cooper animal grazed areas similar to the Wichita Mountains Wildlife Refuge area. The two Kansas individuals yielded no detectable Sr, but exhibited similar Mg concentrations throughout the bulk

of enamel formation. The differences are a reflection of very different elements being consumed by western Kansas bison than those of the Oklahoma animals.

The pilot study presented here indicates that trace element analysis of teeth by microbeam methods is appropriate for examining bison movements. In addition, modern geographical trace element distributions may resemble prehistoric concentrations. The primary result of the pilot study is that quantifiable elemental components exist in the enamel of bison P4s and that bison from various kill episodes can differ from each other, can differ from modern samples, or can overlap with modern samples. Spatial inequalities are known for the distribution of some of the elements that could occur in bison enamel. Matching the regional distributions of select elements with their occurrence in bison enamel promises to shed light on the movement of bison during the time of P4 enamel amelogenesis.

The uncertainties revealed by this study are artifacts of counting statistics. Hydrogen and carbon were not analyzed, and many of the elements analyzed had values below the minimum levels of detection. Increasing the beam current and/or increasing the counting time could potentially improve the detectability of the elements but would risk damaging the samples and be time consuming. The alternative was to find a technique with better sensitivity for minute amounts of trace elements.

THE LA-ICP/MS PILOT STUDY

The electron microprobe provides significant data on Mg, Sr, P, and Ca abundances in tooth enamels, but many other potentially diagnostic elements (e.g. Na, Fe, Mn,

Ba, Pb, U, Cu, Zn, V, K, Al, Se) are likely to be present at concentrations below the detection limit for the electron beam method. A necessary, and logical, extension of this analysis was to use another technique, Laser Ablation – Inductively Coupled Plasma Mass Spectrometry (LA-ICP/MS), which can attain (sub-) ppm detection thresholds and still provide fine spatial resolution on the sample.

LA-ICP/MS (University of Texas, Austin) analysis was performed on the Middle Kill Cooper, the Wichita Mountains Wildlife Area bison, the Kansas sample, and a mandibular P4 premolar from Eagle Pass in southwest Texas (**Figure 3.5**). The teeth were placed directly onto the laser ablation sample stage (not embedded in epoxy or thermoplastic) and analyzed for Na, Mg, Ca, P, Fe, Mn, Sr, Ba, Pb, U, Cu, Zn, V, K, Al, and Se elemental content. Selected elements were chosen because of their presence in enamel, their detectability, their nutritional role, and their probability of being geographical indicators. Testing points were selected every 5 mm from the CEJ to the occlusal surface for each of the tooth samples. Data were calibrated to parts per million using the NIST glasses, with ^{43}Ca as an internal standard.

Quantitative analysis of the bison teeth detected the presence of each of the trace elements except Na, Cu, K, Al, and Se. The LA-ICP/MS results for the P4 premolars indicate that variations occur in Mg, Fe, Mn, Sr, Ba, Pb, U, Zn, and V concentrations throughout the formation of the enamel. Presumably, the changes are a reflection of individual diets and, therefore, geographical range.

The analysis of bison teeth by LA-ICP/MS methods is validated by this pilot study. The Cooper Middle, Wichita, and Kansas individuals indicated remarkably similar

down-tooth elemental concentrations for both the microbeam and LA-ICP/MS analysis. The Kansas sample has less Mg and Sr content than the Wichita and Cooper samples. The Cooper enamel examined by LA-ICP/MS, however, does not mirror the microbeam analysis of the same sample. Instead, the Cooper Middle sample analyzed by LA-ICP/MS has a similar elemental signature as the Cooper Lower specimen examined by the microbeam. Further testing is required to explain the cause of the similar elemental content.

Each of the samples analyzed by LA-ICP/MS methods exhibited distinct elemental concentrations suggesting that geographical differences exist. The results show that southwestern Oklahoma is moderately richer in elemental content of Sr, Mg, U, Mn, and V than western Kansas and southwestern Texas. In addition, Ba is much more abundant, and Zn content is lower in the Wichita sample than the Kansas and Texas specimens. Western Kansas is indicated to be a region with higher Pb and Fe content, and lower amounts of Ba than southwestern Oklahoma and southwestern Texas. The Texas sample shows that southwestern Texas may be defined as an area with lower Fe and Mn, and much less V content than southwestern Oklahoma and western Kansas. Based on this geographical data, then, the movements of prehistoric bison may be assessed.

A major assumption of this study is that modern elemental data can be correlated to the prehistoric trace mineral content of the Southern Plains. The similarities between the Cooper and Wichita samples (also seen using the microbeam methods) during the time of year that Paleoindian-aged bison herds are known to be traveling to western

Oklahoma is rather remarkable. Further, it is apparent that middle Cooper individual grazed in areas with very different elemental content throughout the formation of the enamel. During initial enamel formation, the Cooper bison was in a region with elemental content unlike any of the sampled geographical areas, but by the late summer/early fall had moved to an area similar in elemental content to the modern Oklahoma sample. Inferred from the data, then, is that middle kill Cooper bison ranged farther than the modern samples, and the area grazed prior to moving to western Oklahoma could not have been western Kansas or southwestern Texas.

The pilot studies presented here indicate that detecting trace elemental differences of teeth by microbeam and LA-ICP/MS methods is appropriate for examining bison movements. In addition, modern geographical trace element distributions may resemble prehistoric concentrations. Based on these two pilot studies, it was determined that LA-ICP/MS provided better resolution of a wider array of trace elements and was chosen for use in the rest of the study. Additional trace element data are needed to 1) determine the modern elemental composition of the entire Southern Plains grasslands; 2) confirm the relationship between modern and prehistoric trace mineral contents of specific geographical locations; and 3) identify the movements of *Bison antiquus* and their seasonality so that early Paleoindian mobility strategies may be modeled.

THE SAMPLE

To fulfill these three goals, modern and prehistoric bison samples were collected from and around the southern Plains (**Figure 3.7**). Thanks to the growing interest in bison husbandry that the plains is experiencing today, obtaining modern teeth from animals with well-documented histories for this project was fairly easy (**Figure 3.8**). Twenty-two samples were obtained from managed bison herds on public and private lands including the Wichita Mountains Wildlife Refuge in Oklahoma, Vermejo Park Ranch in New Mexico, Medano-Zapata Nature Conservancy in Colorado, Hugh S.H.A.P.E. Bison Ranch in Texas, Konza Prairie, in Kansas, Smoky Hill Bison Company in Kansas. Coincidentally, the development of the P4 in the third year of life corresponds with the age at which many animals are selected for butchering. Hence, if teeth were not collected from the original bison owners, teeth from the animals have been obtained from regional taxidermy and butcher shops. As with cattle, bison are shipped to a feedlot for finishing prior to butchering. The fattening up of the animals often requires special feeds and nutrients. However, because the enamel amelogenesis is complete prior to slaughtering age, and once complete the enamel does not undergo replacement, the special feedlot diet will not affect the analytical usefulness of the samples as long as individuals selected are at least three years old.

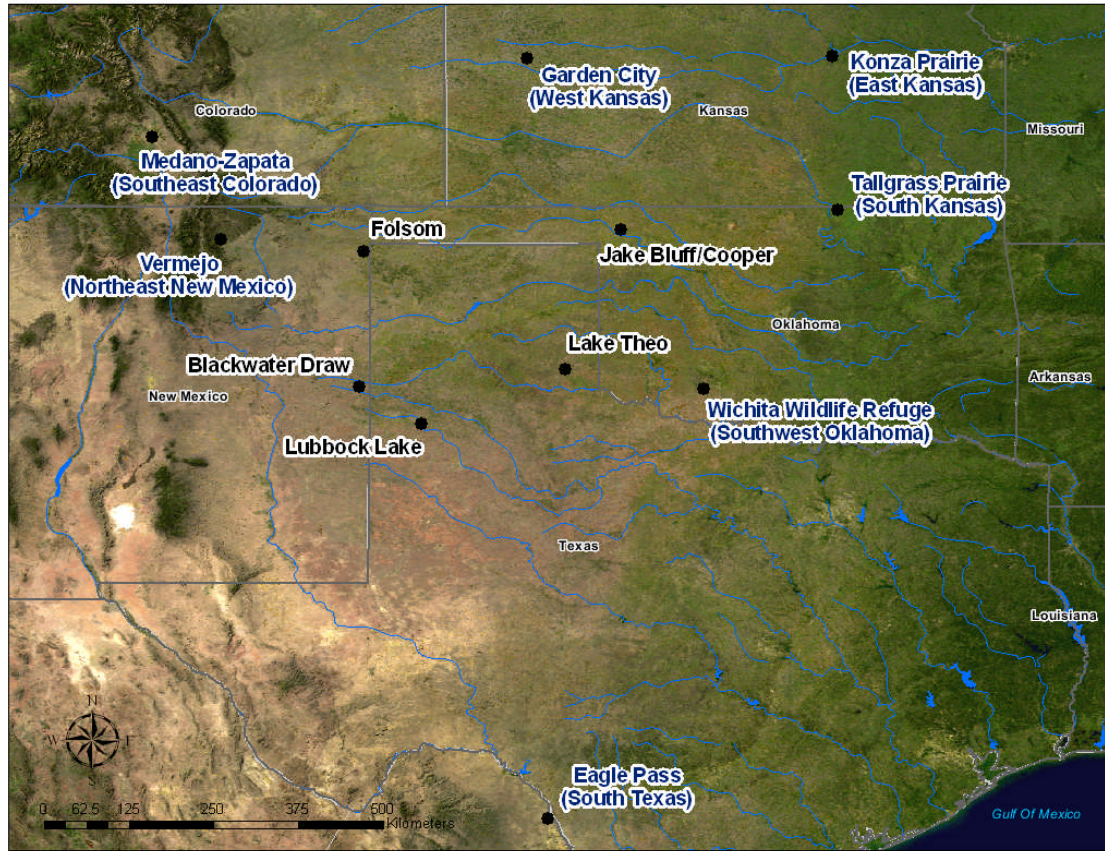

Figure 3.7 Locations from which modern (blue) and prehistoric (black) bison teeth derived for this study.

Figure 3.8 Modern bison mandibles and teeth collected for this study.

Bison teeth derived from Southern Plains sites that are Folsom-age (10,800-10,200 B.P.) and are accompanied by coeval artifacts of Alibates and Edwards chert were sampled. The use of Alibates and Edwards as toolstone by Paleoindian hunter-gatherers is temporally and spatially specific, enabling us to narrow the number of groups involved in bison hunting on the Southern Plains. The prehistoric samples included animals from the early Paleoindian Cooper and Jake Bluff sites (stratified bison kills in northwestern Oklahoma); the Folsom site, New Mexico; Lubbock Lake, Texas; Blackwater Draw, New Mexico; and Lake Theo, Texas (**Table 3.1**). These

sites were chosen because they are all found in the same general area of the plains (similar to that in the hypothetical model presented in Figure 3.4). Fifteen Folsom samples were selected for analysis. These samples were sought from a variety of regions of the plains because they possessed the potential to give a broad spatial characterization of the elemental composition of bison from a variety of regional settings. Most samples were the complete, unworn P4 from three to four year old animals. However, in order to assure adequate sample size, the P4 from older animals were accepted and the elemental results averaged for inclusion in the analysis.

Table 3.1 Table of Prehistoric Sites and Radiocarbon Dates Examined in this Study.

Radiocarbon Sample	Radiocarbon Years BP	Material	Source
Jake Bluff	10,806	bone	Bement and Carter in Press
Cooper Lower	10,600	bone	Johnson and Bement 2009 Johnson and Holliday
Lubbock Lake	10,540	charcoal	1987:12
Cooper Middle	10,530	bone	Johnson and Bement 2009
Cooper Upper	10,505	bone	Johnson and Bement 2009
Folsom	10,490	bone	Meltzer 2006
Blackwater Draw	10,332	charcoal	Haynes et al. 1992
Lake Theo	9,685	humates	Johnson et al. 1982

THE MODERN CONTROL SITES

MEDANO-ZAPATA (SOUTHEAST COLORADO)

The Medano-Zapata Ranch is located in southeast Colorado in the San Luis Valley near the town of Mosca. The ranch comprises 100,000 acres and is the largest Nature Conservancy preserve in the state of Colorado. This preserve lies within a high-elevation (2,286 meters) basin flanked by two mountain ranges: the San Juans and

Sangre de Cristos. The San Luis Valley harbors the Great Sand Dunes National Park (visible from the Medano-Zapata Ranch).

The San Luis Valley of southern Colorado has been called the highest, largest, mountain desert in North America (Trimble 2001). The San Luis Valley is part of the Rio Grande Rift system that extends from central Colorado southward through New Mexico and West Texas into northern Mexico (Knepper and Marrs 1971). The rift system began to form in the Oligocene at the same time that tremendous volcanic eruptions and associated intrusions built up the San Juan Mountains to the west and intrusions took place to the east (Knepper and Marrs 1971). The magnitude of structural movements is demonstrated by more than 9 kilometers of Oligocene-Holocene sedimentary and volcanic fill beneath the floor of the valley juxtaposed with surrounding ranges rising more than 1,800 meters above the valley floor (Knepper and Marrs 1971). Since the creation of the valley, large alluvial fans have accumulated against the mountain front (Knepper and Marrs 1971).

Great Sand Dunes National Monument is located in the San Luis Valley adjacent to the Sangre de Cristo Mountain range. Rising 230 meters above the valley floor, these are the tallest dunes in North America (Johnson 1971). The sand dunes cover an area of about 100 square kilometers, and are situated at approximately 2,500 meters elevation. The sand is blown by prevailing southwesterly wind from alluvial sediments of the San Luis Valley (Johnson 1971). Sand mineralogy indicates that much of the sediment was derived from volcanic rocks of the San Juan Mountains, transported by the Rio Grande, and deposited in the river's huge alluvial fan on the

western side of the valley (Johnson 1971). From there sand, was blown downwind eventually piling up in the Great Sand Dunes. At the mountain front, sand accumulates where the wind is funneled across a low portion of the mountain ridge at three passes: Medano, Mosca, and Music (less than 3,000 meters) (Johnson 1971). The mountain ridge rises to more than 4,000 meters elevation to the south (Blanca Peak) and north (Crestone Peak).

The Rio Grande drains the southern part of the valley through a gorge in volcanic rocks along the Colorado-New Mexico border (Emery 1971). In vicinity of Great Sand Dunes, however, the San Luis Valley is a closed depression with no surface outlet for drainage (Emery 1971). Surface runoff from the Sangre de Cristos soaks into alluvial fans, and ground water migrates toward the low point at San Luis Lake (less than 2,300 meters altitude) (Emery 1971). Abundant ground water gives rise to many ephemeral lakes, wetlands, springs and flowing wells, and supports considerable irrigation in the valley (Emery 1971). Throughout most of the San Luis Valley, depth to ground water is less than four meters (Emery 1971). Ground water is produced from two major aquifers within the valley (Emery 1971). Excessive use of surface water has led to waterlogging of soils in many parts of the valley. Waterlogged soils have become alkaline, and ground water has become highly mineralized from concentration of salts (Emery 1971).

Although closely surrounded by mountains, the San Luis Valley has semiarid to steppe-type climates along the valley floor. The natural vegetation varies from bunch grass and shrub in the open to cottonwood and willow along the streams. Agriculture

in the San Luis Valley is generally concentrated around the Colorado towns of Alamosa, Monte Vista, and Center. Principal crops include potatoes, head lettuce, and barley. The barley grown here is the main supplier for Coors beer company. Less favored areas with shorter growing seasons and less access to water rights tend to be devoted to alfalfa and grazing. Uncultivated land is often covered with "chico," low brush such as rabbitbrush, greasewood and other woody species. Cropland is typically irrigated with large (1/4-mile diameter) center-pivot irrigation systems.

Five bison teeth representing three animals between the ages of two-and-a-half and four years (MZ1 through MZ5) were sampled for this study. Each of the individuals was born and raised on the Medano-Zapata Ranch and did not receive nutritional supplement.

VERMEJO (NORTHEAST NEW MEXICO)

Vermejo is the largest contiguous deeded ranch in New Mexico, comprising 588,000 acres in northeastern New Mexico and southern Colorado. The ranch lies in the Raton Basin, a structural basin about 97 kilometers long and as much as 1.6 kilometers wide that extends from Cimarron, New Mexico, northeastward to Huerfano Park, Colorado, (Woodward 1987). The basin formed during Laramide deformation between about 70 and 50 million years ago as the San Luis Highland rose to the west (Pillmore and Flores 1987). Erosion of the highlands during and after uplift provided sediment that filled the basin (Pillmore and Flores 1987). As the Cretaceous seas receded eastward away from New Mexico, the coastal margin also migrated eastward

(Pillmore and Flores 1987). The Raton Formation, the floodplain and alluvial-plain deposits, were deposited unconformably on top of the Trinidad Sandstone (Pillmore and Flores 1987). The Raton Formation is of Late Cretaceous (about 66 m.y.a.) to Paleocene (about 57 m.y.a.) age and consists of about 335 meters of sandstone, siltstone, mudstone, coal, conglomerate, and carbonaceous shale (Pillmore and Flores 1987). The Vermejo Ranch has elevations ranging from two kilometers in the Raton Basin to four kilometers in the Sangre de Cristo mountains to the west. The region is drained by the Vermejo River that flows southeast to the Cimarron River. Over 60 percent of Vermejo Park is comprised of classic southwestern Ponderosa pine forest, with the southern portion around Cimarron (the location where samples derived) being short grass prairie.

Three bison teeth representing three animals between the ages of 2 and 3 years (V1 through V3) were sampled for this study. Each of the individuals was born and raised on the Vermejo Ranch and did not receive nutritional supplement.

EAGLE PASS (SOUTH TEXAS)

Eagle Pass is in the northwestern section of the Rio Grande plain region in southwest Texas. Elevations range from 165 meters to 183 meters. The Midway Group comprises the major geologic unit of the area and outcrops as a thin arc-shaped belt of sandstones and shales (Roy 1984). It unconformably overlies the marls of the Upper Cretaceous Navarro (Escondido) Formation and is in turn overlain unconformably by the sandstones and shales of the Wilcox Formation (Roy 1984). Due to overlap by

younger formations, usually the Wilcox, the Midway outcrop is not continuous (Roy 1984). Exposures are poor and occur mainly in the vicinity of major streams (Roy 1984). Topography around Eagle Pass exhibits slightly undulating terrain. Native grasses are short and mixed grasses. Less than one percent of the land is considered prime farmland. The Rio Grande drains the area. The principal source of water for domestic and agricultural use is the Rio Grande. Scattered mesquite, some live oak, cat's claw, huajilla, cenizo, and prickly pear are the predominate flora. (Ochoa 2010).

Two bison teeth representing one animal that died at the age of two-and-a-half years (T1 and T2) were sampled for this study. The bison was born and raised on the S.H.A.P.E. Ranch outside of Eagle Pass, Texas and did not receive nutritional supplement.

WICHITA WILDLIFE REFUGE (SOUTHWEST OKLAHOMA)

The 59,020 acres that comprise the Wichita Wildlife Refuge is composed of two rugged ranges of granite mountains that trend nearly east-west and enclose a natural prairie. The first known geologic event in this region took place 550 to 600 million years ago (Early of Middle Cambrian time). The land from northern Texas to north of the present Wichita Mountains sank, forming a basin that filled with sea water. Rivers carried clay, sand, and gravel into this sea, and thick layers of sediments formed. These rocks have been penetrated by deep wells both north and south of the Wichitas, but within the mountains, the only remnants are small outcrops of Meers quartzite. Small masses of this altered sandstone are exposed along Medicine Creek north of

Mount Sheridan and along the road north of the Refuge's Meers entrance. Sometime after the deposition of the sediments, hot lava formed at considerable depth below the surface in the Wichita area. The liquid was forced up into the overlying sediments and spread out between the sedimentary beds. In the Meers area, the lava tore off large fragments of the roof sandstone and altered it to dense compact quartzite. The lava cooled slowly, forming a dark gray to black igneous rock known as gabbro. There are several large outcrops of this rock in the Wichita Refuge. One outcrop straddles the northern boundary, extending 12 miles northwest from west of Lake Lawtonka to North Mountain. Another outcrop, approximately one square mile in area, is present in Cutthroat Gap where it also forms the lower part of the valley walls. A large outcrop of this dark rock occurs north and west of Quanah Parker Lake and extends three miles west to north of the Fish Lakes. An extension of the band may be seen around the Refuge headquarters and Kiowa Lake. After the solidification of the gabbro lava, the area was uplifted thousands of feet. This uplift was accompanied by erosion and the overlying sediments were removed, with the exception of the small remnants of Meers quartzite. The erosion continued exposing the gabbro at the surface and even stripped away part of this rock (U.S. Fish and Wildlife Service 2009).

The next major geologic event took place in the Middle Cambrian time (500 to 550 million years ago). Hot granitic lava developed at considerable depth below the surface and was forced upwards through the overlying gabbro and also in part reached the surface through volcanic vents. The cooling of this hot liquid at depth formed red granite which is the most extensive rock in the Refuge. This contact can

be traced northwest for several miles and dips to the south. The granites were intruded at the contact between gabbro and its own volcanic pile (the Carlton rhyolite), perhaps with minor sediment cover on the gabbro. (U.S. Fish and Wildlife Service 2009).

The mountains of the Wichita region were formed some 300 million years ago (Pennsylvanian period). They were created by a tremendous uplift accompanied by large folds and faults. Some of the faults were miles in length and produced large blocks. Some of these settled with respect to others, and the large flat areas bordering the Scenic Highway in the central part of the Refuge probably originated by faulting. The mountains originally were considerably higher than the present ones as erosion has stripped off the upper parts and deposited this material in the intervening flats, reducing the relief. Most of this erosion took place in Permian time (some 250 million years ago) and produced extensive gravel deposits. Remnants of these gravels may be seen north of Crater Lake, north of Lake Elmer Thomas, east and south of Lost Lake, and in several other parts of the Refuge. Granite is the dominant rock of the Refuge, and the gravels formed by erosion are mainly composed of granite fragments. There are unconsolidated well-rounded boulders 6 to 18 inches in diameter, known as cobblestones, surrounded by yellow-to-brown clay. Below the weathered surface they are well cemented (U.S. Fish and Wildlife Service 2009).

The main geologic event that has taken place since is the erosion of most of the Permian gravels that once covered this area. In recent times, some newer gravels have been deposited along the small streams and in the flats. These can be seen around

Lake Lawtonka, along Sandy Creek, Wolf Creek, and in other areas of the Refuge. Boulder slides in the drainage depressions are common on many of the steep slopes. One of the best examples of boulder accumulation is the "River of Boulders" on the south side of Mount Scott (U.S. Fish and Wildlife Service 2009).

Approximately 20,000 acres of the Wichita Wildlife Refuge are open mixed grass prairie, with the remainder being forest and rock outcroppings. The grasslands are dominated by little bluestem, with Indian grass, big bluestem, switchgrass, sideoats grama, hairy grama, and blue grama having a large percentage of the overall species composition. The forested areas are dominated by post oak, blackjack oak and eastern red cedar. (U.S. Fish and Wildlife Service 2009). Generally speaking, drainages and creeks of the Wichita Wildlife Refuge flow south to the Red River.

Two bison teeth representing two animals that expired at the ages of three and four years (W1 and W3) were sampled for this study. The bison were born and raised on the Wichita Wildlife Refuge and did not receive nutritional supplement.

TALLGRASS PRAIRIE (SOUTH KANSAS)

The Tallgrass Prairie Preserve is located approximately 24 kilometers north of Pawhuska, Oklahoma and comprises approximately 230,400 acres. Two hundred to 300 million years ago the gray and white limestone and chert (the latter commonly called "flint") began to form on the Permian Sea floor. The Flint Hills, as they have come to be known, cross east central Kansas from the north near the Nebraska border and extend south into Oklahoma, where they are called the Osage Hills. The region

consists mainly of alternating layers of limestone and shale. The unique, stair-step landscape of the Flint Hills was formed through a geological process called differential erosion. The limestone, with concentrations of flint, is harder and more erosion resistant than the softer layers of shale in between. The tougher limestones and flint form prominent benches on the hillsides and cap the hilltops, while the softer shales in between are slowly worn away, making thin, gravelly soil. The Flint Hills region is characterized by thin soils, limestone outcrops, vegetation-covered shale intervals between the limestones, and deeply cut valleys, exposing the geology beneath the soil. The Tallgrass Prairie consists of big bluestem, little bluestem, switchgrass, and Indiangrass with oaks and cedars along larger order drainages. Sand Creek drains the Preserve and flows east to Bartlesville, Oklahoma (The Nature Conservancy 2010).

Four bison teeth representing four animals that expired at 2 ½ (TGP#18), 13 ½ (TGP#6), 3 (TGP#3), 3 ¾ (TGP#2), and 5 (TGP#12) years of age were sampled for this study. TGP#18 is a female and was transferred from the Wichita Wildlife Refuge to the Tallgrass Prairie at the age of six months. She was killed by a vehicle. TGP#6 is a female and was born in Lovell, Wyoming. She was transferred from Bartlesville, Oklahoma to the Tallgrass Prairie at the age of 11.5 years and died of unknown complications. TGP#3 is a female and was transferred from Bartlesville, Oklahoma to the Tallgrass Prairie at the age of 1.5 years. She died giving birth. TGP#2 is a male and was transferred from Bartlesville, Oklahoma to the Tallgrass Prairie at the age of 2.5 years and died in a chute accident during roundup. TGP#12 is a male and was transferred from Bartlesville, Oklahoma, to the Tallgrass Prairie at the age of 2.5

years and was hit by lightning causing its immediate death. None of these animals were provided supplement.

KONZA PRAIRIE (EAST KANSAS)

The Konza Prairie is located in the Flint Hills region of northeastern Kansas, approximately 10 kilometers south of the city of Manhattan. Konza is an 8,600 acre native tallgrass prairie preserve owned by The Nature Conservancy and Kansas State University and operated as a field research station by the Kansas State University Division of Biology. The Flint Hills are steep-sloped and overlain by shallow limestone soils unsuitable for cultivation. The Konza Prairie has a continental climate characterized by warm, wet summers and dry, cold winters sufficient to support woodland or savanna vegetation; consequently, drought, fire and grazing are important in maintaining this grassland. The vegetation at Konza is primarily (greater than 90 percent) native tallgrass prairie, dominated by perennial C4 grasses, such as *Andropogon gerardii*, *Sorghastrum nutans*, *Panicum virgatum* and *Schizachyrium scoparium*. The geology causes a relatively complex hydrologic system, but surface waters drain north to the Kansas River (Konza Prairie Biological Station 2010).

Two bison teeth representing one two and a half (EVA 2.5) and one three year old (EVA 3) were sampled for this study. The bison were born and raised on the Konza Prairie and received nutritional supplement (Vigortone No. 32S Plus), which is known to contain calcium, phosphorus, salt, magnesium, potassium, copper, selenium, and zinc.

GARDEN CITY (WEST KANSAS)

Garden City is located on the Arkansas River in southwestern Kansas. The Arkansas River Lowlands follows the course of the Arkansas River through southwest and south central Kansas, and dissects the High Plains in and around Garden City. The broad floodplain contains large quantities of Quaternary sand and silt carried from the Rocky Mountains by the river (Mandel 1994:46, 49). The ancestral Arkansas River has meandered for millions of years, leaving reworked alluvium in its many abandoned channels (Mandel 1994:49). North of the Arkansas River, the underlying rocks are part of the Pennsylvanian system, consisting mostly of shale, frequented by intervals of limestone beds and some sandstone (Fenneman 1938:606-607). To the south, limestone is scarce and the Permian sandstones thicken (Fenneman 1938:607). Sand dunes occur on the south side of the plain formed by the prevailing winds from the glaciers to the north during the Pleistocene. The dominant vegetal species in the area is sand sagebrush. (Hulett et. al 1988). *Sporobolus cryptandrus*, *Bouteloua gracilis*, and abundant annuals characterize the understory vegetation (Hulett et. al 1988). The area is drained on the surface by the Arkansas River and is underlain by the Ogallala Aquifer.

Four bison tooth samples from three individuals between three and seven years of age (GCK1 through GCK4) were sampled for this study. The bison were born and raised in Garden City and received no nutritional supplement. The samples were obtained from a taxidermist in Yukon, Oklahoma.

THE ANCIENT KILL SITES

FOLSOM

The Folsom site, in Colfax County, New Mexico, is one of the most widely known archaeological localities in North America. The Folsom site is located at an elevation of 2,109 meters. The local bedrock is Smoky Hill shale of Cretaceous age (Scott and Pillmore 1993). The shale is unconformably overlain by late quaternary sediments. These include the Folsom Formation overlain by the McJunkin Formation and the Wild Horse Formation (Anderson and Haynes 1979). M. Balakrishnan et al. (2005) posit C4 plant communities made up the majority of vegetation in the area at the time bison were killed in the arroyo.

Thirty-two bison were trapped and killed in two areas of the Folsom site: the paleochannel of Wild Horse Arroyo, and a steep-sided tributary that fed into it (Meltzer 2006). The site is dominated by low-utility bone elements and broken projectile points (Meltzer 2006). The bison remains in the tributary are mostly in primary context, and underwent rapid burial beneath fine-grained (dominantly aeolian) sediments, which in turn were subsequently armored by shingle shale (Meltzer 2006). The small lithic assemblage is dominated by projectile points and comprised of material mostly from two sources in the Texas panhandle (Alibates and Tecovas) (Meltzer et al. 2002:28), several hundred kilometers southeast of the site. It also includes stone obtained from sources at comparable distances north and northwest of the site (Meltzer 2006). Multiple radiocarbon assays on bone amino acids from different individuals in the bison herd indicate an average age of

approximately 10,500 14C yr B.P. (Meltzer et al. 2002). Patterns of bison dental eruption and wear suggest that the kill occurred in the fall (Hofman 1991).

Two bison tooth samples from two individuals (M17-24-141 and M17-24-97) from the Folsom site were analyzed for this study.

BLACKWATER DRAW

The Blackwater Draw site, in Curry County, New Mexico, is often referred to as the “Clovis type-site” and is one of the most significant Plains Paleoindian localities (Boldurian and Cotter 1999, Haynes 2002:62; Holliday 1997:59). The majority of rocks and sediments that make up the Llano Estacado, the primary landform that comprises the Southern High Plains, are Cenozoic deposits (Holliday 1997:10). The Blackwater Draw site is located in a paleobasin cut into the Late Quaternary Blackwater Draw Formation found across the Southern High Plains and is the major surficial eolian deposit overlying and often cutting into the Miocene-Pliocene Ogallala Formation (Haynes 1997:11, 59). The Blackwater Draw site is located in a tributary paleobasin characterized by an abundance of diatomaceous muds indicative of reduced water velocity or stream discharge in which the water level seasonally fluctuated (Boldurian and Cotter 1999:22; Holliday 1997:69, 89, 182). Boldurian and Cotter (1999:22) suggested, that as a result of global climate changes from the late Pleistocene to the early Holocene, these basins or ponds were probably few in number and by the end of Folsom times (10,000 B.P.) developed into marshy slack-water environments. The Late Quaternary fill observed at Blackwater Draw revealed a

hydrologic shift from flowing water to standing water to the almost complete disappearance of surface water and the accumulation of eolian sediment (Haynes 1997:51-52). During the late Paleoindian period, environmental research suggests the Paleoindian habitat at Blackwater Draw was warm and dry, spring discharge was reduced to a minimum and surface water disappeared for extended periods causing desiccation that thinned vegetation and fauna and increased eolian activity creating dune field and sand sheets. The once active draws, such as Blackwater Draw, became choked with eolian sediment (Boldurian and Cotter 1999:23). Generally speaking, the Folsom period is characterized by lush vegetation around shallow water and the presence of early Holocene fauna of aquatic and terrestrial species that included *Bison antiquus*. The natural vegetation of the Llano Estacado is mixed-grass prairie grassland dominated by short-grass native plants such as grama (*Bouteloua sp.*) and buffalo grass (*Buchloe dactyloides*) (Holliday 1997:9).

The large lithic assemblage is dominated by projectile points of several material types. The Clovis period inhabitants of Blackwater Draw Locality No. 1 primarily used Alibates agate, while the Folsom period inhabitants preferred Edwards chert as the principal material utilized for their stone tools. In addition, throughout the Paleoindian occupation of Blackwater Draw, orthoquartzites and Tecovas jasper were used, but to a much less extent (Boldurian and Cotter 1999:23). Alibates agate, Edwards chert, and Tecovas jasper are primarily restricted to the eastern margins of the Llano Estacado while the orthoquartzite material comes from the nearby Dakota formation (Boldurian and Cotter 1999:23).

Blackwater Draw Locality No. 1 Clovis and Clovis-age (11,630-11,040 BP) features yielded eight mammoths (*Mammuthus columbi*), two *Bison antiquus* bone beds, and two campsites all located near spring conduit or outlet channels (Boldurian and Cotter 1999:22; Haynes 2002:62, 64, 190; Holliday 1997:64-67). Folsom and Folsom-age (10,500-10,000 BP) features contained *Bison antiquus* bone beds, Folsom projectile points, and unfluted projectile points (Boldurian and Cotter 1999:27; Holliday 1997:67-69). The Paleoindian hunters at Blackwater Draw exploited small bison groups of six or fewer animals that they ambushed near lake edges. No season of death has been ascertained (Bement 1999:6). The Folsom-age bone bed deposits contained a minimum number of individuals of two to five *Bison antiquus* (Bement 1999:159).

Folsom-aged bison tooth samples from two individuals (LA3324-1 and LA3324-2) from the Blackwater Draw site were analyzed during this study.

LUBBOCK LAKE

The Lubbock Lake site is located just outside the city of Lubbock in Lubbock County, Texas. The majority of rocks and sediments that make up the Llano Estacado are Cenozoic deposits (Holliday 1997:10). Lubbock Lake is in, and above, an entrenched meander of lower Yellowhouse Draw that cuts through the Late Quaternary Blackwater Draw Formation and into the Pliocene Blanco Formation, the latter of which forms the local bedrock (Holliday 1997:76). Yellowhouse Draw consists of alluvial sand and gravel fill (Holliday 1997:78). Lubbock Lake sediment

consists of Pliocene clays that had been exposed at the surface for approximately 6,000 years prior to being buried by middle-Holocene sediments. Surface erosion and bioturbation caused mixing of Late Quaternary occupation debris into the Pliocene bedrock (Holliday 1997:79). Like Blackwater Draw, Lubbock Lake sediment consists of diatomaceous mud deposited under standing lake waters (Holliday 1997:83). Unlike Blackwater Draw, Lubbock Lake is not located within a paleobasin, but is instead within a draw (Holliday 1997:89). Generally speaking, the Folsom period is characterized by lush vegetation around shallow water and the presence of early Holocene fauna of aquatic and terrestrial species that included *Bison antiquus*. Today, the natural vegetation of the Llano Estacado is mixed-grass prairie grassland dominated by short-grass native plants such as grama (*Bouteloua* sp.) and buffalo grass (*Buchloe dactyloides*) (Holliday 1997:9).

The small lithic assemblage recovered from Lubbock Lake suggests the Paleoindian inhabitants almost exclusively used Edwards Plateau chert as their toolstone source (Bement 1999:160; Johnson 1997:55). The Lubbock Lake site contained multiple bone bed features within a gravelly point bar that contained various animal remains, some of which exhibited evidence of butchering, and include mammoth (*Mammuthus columbi*), extinct bison (*Bison antiquus*), extinct horse (*Equus mexicanus* and *Equus francisci*), extinct camel (*Camelops hesternus*), extinct giant armadillo (*Holmesina septentrionale*), and extinct short-faced bear (*Arctodus simus*) (Holliday 1997:78-79). Like Blackwater Draw, the Paleoindian hunters at Lubbock Lake exploited small bison groups of six or fewer animals that were ambushed near lake edges (Bement

1999:6). Lubbock Lake Folsom-age deposits contained a minimum number of individuals of three *Bison antiquus* (Bement 1999:159).

Three separate Pleistocene occupations have been identified at Lubbock Lake. The earliest occupation, dating from 11,700 to 11,100 B.P. contained human modified bison bones, which based on mandibular dental eruption and wear patterns, suggested the bison were between 3.6 years and 5.6 years or older indicating a fall death (Johnson 1997:51). The second Pleistocene occupation, dating to 11,100 BP, contained seven megafaunal species, that included bison, exhibiting human modification, but no season of death could be ascertained (Johnson 1997:51-52). The third Pleistocene occupation, dating to 10,500 to 8,000 B.P., contained repeatedly used bison kill and butchering locales exhibiting human modified bison bones, which indicated at least one Folsom-age fall-winter kill (Johnson 1997:52-53).

One Folsom aged bison tooth sample (41-LU1) from the Lubbock Lake site was analyzed during this study.

LAKE THEO

The Lake Theo site, located in Briscoe County, Texas, is the only Folsom bison kill site located in close proximity to a high-quality chert source, Tecovas Jasper (Buchanan 2002). The Lake Theo site is on the Rolling Plains immediately east of the High Plains escarpment (Buchanan 2002:122-123; Holliday 1997:48), and on a Holocene terrace at the southern edge of the artificial Lake Theo, created by the damming of Holmes Creek (Buchanan 2002:122). The terrace is composed of Late

Quaternary alluvial, floodplain, and eolian deposits situated within the “breaks” ecotone (Buchanan 2002:124). The “breaks” refers to the regional Paleozoic and Mesozoic sedimentary rocks deposited across the Permian and Triassic-age redbeds that are severely eroded and exposed along the eastern escarpment of the Southern High Plains (Buchanan 2002:124). Generally speaking, the Folsom period is characterized by lush vegetation around shallow water and the presence of early Holocene fauna of aquatic and terrestrial species that included *Bison antiquus* (Holliday 1997:183-184). The environment of the region, during Folsom occupation, was savannah like (cooler and drier than during the Clovis period) with perennial streams and freshwater ponds. The water level of ponds fluctuated seasonally, producing diatomaceous muds that by the end of the Folsom period evolved into muddy marshes (Holliday 1997:183-184). Today, the natural vegetation of the Southern Plains is mixed-grass prairie grassland dominated by short-grass native plants such as grama (*Bouteloua* sp.) and buffalo grass (*Buchloe dactyloides*) (Holliday 1997:9).

Lake Theo contains two distinct bone beds and a large lithic assemblage. The lithic assemblage suggests the inhabitants primarily used Edwards Plateau chert as their toolstone, with lesser amounts of Alibates and Tecovas jasper (Buchanan 2002:122). The lower bone bed contained extinct bison and Folsom artifacts (ca. 11,000-11,900 BP) and the upper bone bed contained extinct bison and Plainview artifacts (ca. 5,500 BP) (Buchanan 2002:125-126; Holliday 1997:48). The Folsom-age bone bed contained a minimum number of individuals of 12 *Bison antiquus* and the

reconstructed season of death indicated a fall kill (Bement 1999:159; Buchanan 2002:142).

One Folsom aged bison tooth sample (THEO) from the Lake Theo site was analyzed for this study.

JAKE BLUFF

The Jake Bluff site is located in Harper County, Oklahoma, and is a stratified Paleoindian site within and adjacent to a paleo-arroyo. Jake Bluff is located at an elevation of 610 meters (Bement and Brosowske 1999:17). The site is located on a small hill on a dissected toeslope within the Beaver River floodplain (Bement and Carter 2010:10). The arroyo cuts into the Permian Redbeds, or Cloud Chief Formation, which are overlain by the Tertiary age Ogallala Formation. The more recent Quaternary age alluvium derived from the Ogallala Formation contains Pleistocene to Holocene deposits that constitute the dune sediments observed across the region (Bement, Schuster, and Carter 2007:4). Between 11,000 and 9,800 B.P. sediments consisted of fine sand alluvium with “a short-duration aeolian event” (Bement and Carter 2010:7). These sediments supported a plant community that consisted primarily of C4 (Chloridoidae and/or Panicoid) grasses and members of the sunflower family (High-spine Asteraceae) (Bement and Carter 2010:7).

In contrast to the small opportunistic bison kill sites located near water sources such as Blackwater Draw and Lubbock Lake, Jake Bluff exemplifies Paleoindian hunters deliberately trapping greater numbers of bison in an arroyo trap (Bement and Carter

2003:7). The Jake Bluff site was a steep-walled, dead-end arroyo trap of nearly two dozen bison. The Clovis component at Jake Bluff has an average date of 12,838 cal B.P., whereas the Folsom component has not yet yielded a reliable date (Bement and Carter 2010:22, 24).

The Jake Bluff site bone assemblage contained a minimum number of individuals of 22 *Bison antiquus* and one bear (*Ursus americanus*) (Bement and Carter 2010:18). Based on analyzing tooth eruption and wear patterns of 13 mandibles, bison from the Clovis component at Jake Bluff were killed during the fall, or more specifically late September or October (Bement and Carter 2010:19). The Clovis component lithic assemblage at Jake Bluff was dominated by Alibates chert, while the Folsom component contained a projectile point of Edwards chert (Bement and Carter 2010:15-18, 28).

Two Clovis age bison tooth samples from two individuals (34HP60 and 34HP102) from the Jake Bluff site were analyzed during this study.

COOPER

The Cooper site is located in Harper County, Oklahoma, in a paleo-arroyo along the floodplain margin on the Beaver River (Bement 1999:7). The arroyo cuts into the Permian Redbeds, or Cloud Chief Formation, which are overlain by the Tertiary age Ogallala Formation. The more recent Quaternary age alluvium derived from the Ogallala Formation contains Pleistocene to Holocene deposits that constitute the dune sediments observed across the region (Bement, Schuster, and Carter 2007:4).

Between 11,000 and 9,800 B.P. sediments consisted of fine sand alluvium with “a short-duration aeolian event” (Bement and Carter 2010:7). These sediments supported a plant community that consisted primarily of C4 (Chloridoideae and/or Panicoid) grasses and members of the sunflower family (High-spine Asteraceae) (Bement and Carter 2010:7).

The Cooper site consists of three discrete *Bison antiquus* bone bed deposits in a paleo-arroyo dating to 10,900 to 10,200 B.P. (Bement 1997; Bement 1999; Bement and Brosowske 1999). Folsom hunters carried out three separate kills during the late summer to early fall trapping bison in a steep-sided arroyo (Bement 1997:95; Bement 1999:127; Bement and Brosowske 1999:40; Bement and Carter 2003:4). The total number of *Bison antiquus*, based on minimum number of individuals, for the Upper, Middle, and Lower Kills at the Cooper site is 29, 29, and 20, respectively (Bement 1999:127). The presence of completely articulated skeletons suggests a gourmet style of butchering in that the meat was filleted from the carcass (Bement 2003:29). The raw materials represented in the lithic assemblage at the Cooper site are highly variable. Of 33 Folsom projectile points discovered at this site, the Upper Kill contained primarily Alibates (n=10, 77 percent), the Middle Kill contained seven points all of Edwards Plateau chert, and the Lower Kill contained almost equal numbers of Edwards (n=4, 57 percent) and Alibates (n=3, 43 percent) (Bement 1999:138,141-142).

Six Folsom age bison tooth samples, two individuals from each kill level at the Cooper site (34HP45-494, 34HP45-671, 34HP45-837, 34HP45-718, 34-HP45-856, 34HP45695) were analyzed during this study.

THE ABLATION ANALYSIS

Each tooth was analyzed for 65 elements across five increments separated by 5mm from the top of the tooth to the CEJ to identify inter-tooth variability (**Appendix A**). In addition, each tooth was analyzed as a bulk sample, averaging the entire down-tooth elemental content to assess intra-tooth geographical differences. The GBC Optimass orthogonal time-of-flight (TOF) ICP-MS and New Wave 213 LUV Laser Ablation System housed at The Institute for Integrated Research in Materials, Environments, and Society (IIRMES), California State University, Long Beach, was used for the current study. The TOF mass discriminator system provides for essentially simultaneous analysis across the mass spectrum. Although uncertainties are known, this form of analysis is advantageous where the element signal is highly transient but needs to be resolved temporally. Further, the technique causes only minute damage to tooth samples (**Figure 3.9**). The instrument has an attached New Wave 213LUV Laser Ablation system that permits solid sample, in-situ analysis of samples. The laser was fired at a repetition rate of 5 Hz. The laser Gaussian beam was then focused, using a x15 objective (reflective) or x1.75 silica lens, on a sample placed in a cell located on a manual X-Y-Z mechanical stage. Such focusing yielded ablation pits of 50 μm (x15 objective, first and third ablation sessions) to 200 μm

(x1.75 silica lens, first ablation session) in size on inclusions and glasses analyzed in single-point mode. Pulse energy of 1.3 mJ/pulse (using the x15 objective for inclusions) to 7.5 mJ/pulse (using the silica lens for reference glass) was applied during the first ablation session. Pulse energy of 2 mJ/pulse (with the objective) was used for the analysis of enamel during the second session. Pulse energy of 1.5 mJ/pulse (with the objective) was used to analyze reference glasses in the third ablation session. The 65 elements were measured with dwell times of 10 ms. The total acquisition time for one complete analysis was about two minutes. Whole teeth were placed in the laser chamber. The laser chamber was large enough to hold a premolar or a molar, and in some instances two premolars. A raster drawn on every surface was pre-ablated to remove potential contaminants on the enamel surface. After the pre-ablation pass, data collection was initiated on the ICP-MS. Data from two glass standards (NIST SRM 612 and 614 glass) were recorded before and after each set of samples in the laser chamber, in order to provide precise calibrations that compensate for instrumental drift. Data were calibrated to parts per million using the NIST glasses, with ^{43}Ca as an internal standard. In most cases, the SRM614, with concentrations of most elements less than 1 ppm, was used for calibration.

Figure 3.9 Degree of damage that can occur to enamel during ablation.

CHAPTER 4: THE PERIODIC TABLE, THE NUMBERS, AND THE BLENDER

The purpose of examining a wide variety of elements is to identify potential minerals whose distribution is limited, not abundant, or not well known, and from a suite of signature elements that compose a spatial landscape on which to impose prehistoric tooth elemental composition data. The results of such an undertaking reveal thousands of lines of data that are not useful for this study because the elemental signatures do not reflect diet, or because they tell us nothing about potential post mortem diagenetic effects. However, the basic approach to identifying trace elemental compositions on a landscape and where bison herds were during the mineralization of their enamel is simple: Reference groups are defined among the unknowns, and sources for the various unknown groups are then determined by sampling knowns and comparing them to the unknown groups by determining the abundance of minerals, or by determining regional geologic variation. In our sample, the modern bison teeth samples provide information about the abundance of minerals in a wide geologic setting. Complexity is introduced by the nature of prehistoric unrestricted bison herds whose movement may cause the abundance of minerals in their teeth to vary significantly from modern bison samples that expired in similar geographic regions but in very different environmental and temporal settings. A further difficulty, which is the primary focus of this chapter, is the mathematical pattern recognition techniques employed to segregate the unknown bison tooth samples. Thus, analytical

approaches should be referenced to the nature of the samples analyzed and the assumptions of multivariate techniques.

DATA TRANSFORMATIONS

Transformations can be applied to the data so they will more closely follow a normal distribution or to eliminate the effect of greatly differing magnitudes of the elemental concentrations (Neff 2002:16). Log transformations are justified in part by the argument that the distributions of many elements are so skewed that transformation to log concentrations produces more near normal distributions, which are assumed by many statistical procedures (Ahrens 1965; Baxter 1994; Beiber et al. 1976; Harbottle 1976). In some cases, what seems to be log normality may be an artifact of detection limits of particular techniques, which may cut off the lower range of an element's observed concentration range (Neff 2002:16). Baxter (1994:46-47) argues that normality is not an essential requirement of most multivariate methods used in compositional data analysis, and that multimodal distributions of elemental concentrations due to the presence of multiple compositional groups would make it difficult to judge the utility of taking logarithms. However, for data analysis in which trace elemental concentrations are employed, some form of scaling is necessary to keep the variables with the larger concentrations from having excessive weight in pattern recognition and statistical analysis (Neff 2002:17). Using transformations that equalize the magnitude of the measurements and the amount of variation is in keeping with one of the premises of numerical taxonomy. That is, no individual variable should assume more weight than another in an analysis involving the calculation of

resemblance (Harbottle 1976; Sneath and Sokal 1973). All elemental concentrations were log transformed for the purposes of this study.

STATISTICAL ANALYSIS

According to Neff (2002:15), a data matrix produced by instrumental neutron activation analysis usually contains at least 25 metric variables (elemental concentrations) determined for an even larger number of observations (bison teeth). Each observation is also described by a number of descriptive variables, which may be metric or nonmetric and may pertain to both the tooth's archaeological context and to its inherent properties (Neff 2002:15). Quantitative analysis in a provenance investigation aims to extract structure from the data matrix in such a way that as many as possible of the individual teeth will be assigned a specific source location in geographic space (Neff 2002:15).

One method used to search for structure in a data matrix is characterized as "analysis of variance" (Neff 2002:15). This approach focuses on interrelationships among variables in the data rather than similarities among the observations (Neff 2002:15). In a univariate approach, t-tests may be employed to compare elemental concentration means and standard deviations from the two contexts, with an inference of variation in source composition drawn if the t-tests suggest statistically significant differences. An "Each Pair, Student's t" computes individual pairwise comparisons applying a test that is sized for individual comparisons. To compare these tests across several data matrices of numerous teeth samples, a circles plot is used as a visual representation of

group means. The illustration in **Figure 4.1** shows the alignment of comparison circles with the confidence intervals of their respective group means for the Student's t comparison. Other comparison tests widen or shorten the radii of the circles.

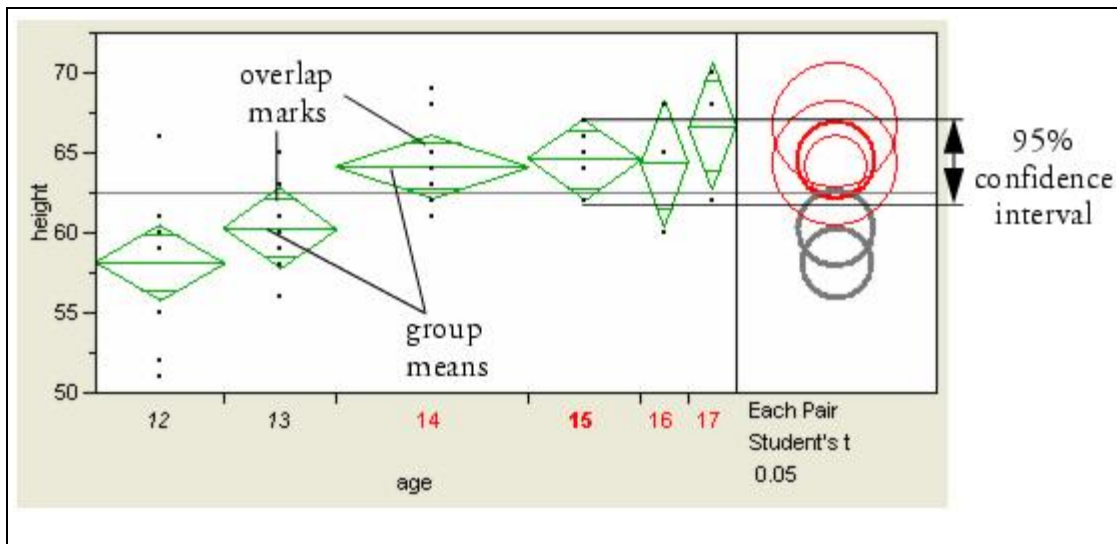

Figure 4.1 Visual comparison of group means.

One can compare each pair of group means visually by examining how the comparison circles intersect. The outside angle of intersection illustrates whether group means are significantly different (**Figure 4.2**). Circles for means that are significantly different either do not intersect or intersect slightly so that the outside angle of intersection is less than 90 degrees. If the circles intersect by an angle of more than 90 degrees or if they are nested, the means are not significantly different. More elaborate examples of the “analysis of variance” employ multivariate analysis and examine interactions among descriptive categorical variables such as location and time period in determining the structure of chemical variation. A variant of this

approach is to calculate linear discriminant functions for groups defined purely on the basis of descriptive categories (Neff 2002:15).

Figure 4.2 Angle of intersection and significance.

The current study employed multivariate analysis to define interrelationships among elemental concentrations among both modern and prehistoric samples to assess which elements may reflect diet, diagenesis, or metabolic composition; and among only the modern bison tooth samples to define geographic distributions across the landscape. Analysis of all samples revealed a set of isotopes and elements that proved more useful to determining diet and bison movement. These observations are boron (B), sodium (Na), chlorine (Cl), potassium (K), zinc (Zn), strontium isotope ratio ($Sr87/Sr86$), and lead (Pb). How these elements are distributed across the landscape will be discussed later.

Elemental composition is thought to be a factor of a metabolic presence within teeth for those elements not usually known to indicate diet while showing a linear and very trace distribution among both modern and prehistoric tooth samples. These elements are titanium (Ti), gallium (Ga), bromine (Br), molybdenum (Mo), iodine (I), cesium

(Cs), and cobalt (Co). A greater understanding of how elements move through the lithosphere and how these elements are distributed in bone and teeth may help identify some of these elements as useful indicators of bison diet and movement in the future. Observations that revealed modern teeth samples to have an absence or very low concentrations of a particular element while prehistoric teeth indicated a high presence of the same element are thought to represent diagenetic change of the older samples over time. Elements that make up this group include arsenic (As), rubidium (Rb), yttrium (Y), zirconium (Zr), tin (Sn), antimony (Sb), tungsten (W), mercury (Hg), and uranium (U), as well as the rare earth elements dysprosium (Dy), lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), samarium (Sm), europium (Eu), and gadolinium (Gd). Future studies that closely examine how and when minerals are incorporated into bone and teeth post mortem may also assist in identifying some of these elements as dietary or geographical indicators. Also, elements such as uranium may prove to be excellent indicators for obtaining absolute dates on bison teeth as preliminary data observed during this study shows a gradual increase of U over time.

T-tests of only the modern teeth for the elements B, Na, Cl, K, Zn, Sr88/Sr87, and Pb showed some very interesting patterns regarding the distribution of these elements across the landscape (**Figures 4.3 through 4.9**).

Figure 4.3 Oneway analysis of LogB by location, and t-test diagram. This plot shows the southern Kansas samples and southwestern Oklahoma samples are significantly different from the remaining samples.

Figure 4.4 Oneway analysis of LogNa by location, and t-test diagram. This plot shows that nearly all of the samples have a unique elemental signature with western Kansas, southwestern Oklahoma, and south Texas clustering together; and northeastern New Mexico and eastern Kansas clustering together.

Figure 4.5 Oneway analysis of LogCl by location, and t-test diagram. This plot shows that nearly all of the samples have a unique elemental signature with western Kansas and south Texas clustering together; and northeastern New Mexico and eastern Kansas clustering together.

Figure 4.6 Oneway analysis of LogK by location, and t-test diagram. This plot shows that northeastern New Mexico, south Kansas, south Texas, and southeastern Colorado have similar elemental signatures .

Figure 4.7 Oneway analysis of LogZn by location, and t-test diagram. This plot shows that southern Texas, southwestern Oklahoma and western Kansas samples have similar elemental signatures .

Figure 4.8 Oneway analysis of LogSr87/Sr86 by location, and t-test diagram. This plot shows that northeastern New Mexico and west Kansas samples have similar elemental signatures .

Figure 4.9 Oneway analysis of LogPb by location, and t-test diagram. This plot shows that eastern Kansas, northeastern New Mexico, southern Kansas, and western Kansas samples have similar elemental signatures .

The B t-test shows that we may expect to find higher concentrations of B in places like south Kansas and southwestern Oklahoma that are markedly different from the other places sampled during this study. T-tests for Na and Cl indicate similarities in how these elements are distributed across the landscape and many of the locations are unique in the concentration of these elements. K elemental concentrations are shown to be significantly higher for southwestern Oklahoma samples, and significantly lower for east and west Kansas than the remaining samples. South Texas, southwestern Texas, and west Kansas show significantly higher concentrations of Zn than the other samples. Sr87/Sr86 concentrations are highest in northeastern New Mexico and west Kansas, while east Kansas, south Kansas, and southeastern Colorado show the lowest concentrations. East Kansas, northeastern New Mexico,

south Kansas, and west Kansas have significantly low Pb concentrations and southwestern Oklahoma stands out with very high concentrations.

T-tests were also used to determine interrelationships among each prehistoric site and the modern samples to compare elemental concentration levels and variation (**Appendix B**). Sr87/Sr86 serves as an example to illustrate the kinds of patterns observed in the data matrix (**Figures 4.10 through 4.17**).

Figure 4.17 Oneway analysis of LogSr87/Sr86 by location (modern and Lake Theo samples) and t-test diagram.

Figure 4.10 shows that the Upper Kill Cooper sample has isotopic ratios that are statistically lower than northeastern New Mexico and south Texas. The implication is that Upper Kill bison did not traverse at least those two areas. Figure 4.11 shows that the Middle Kill Cooper sample has ratios that are statistically lower than all of the modern samples. The implication is that Middle Kill bison did not traverse any of the modern sample areas. Figure 4.12 shows that the Lower Kill Cooper sample has isotopic ratios that are statistically lower than all of the modern samples. The implication is that the Lower Kill bison did not traverse any of the modern sample areas. Figure 4.13 shows that the Jake Bluff sample has ratios that are statistically lower than all of the modern samples except for southeastern Colorado. The implication is that Jake Bluff bison grazed in an environment with similar Sr87/Sr86 ratios as modern bison in southeastern Colorado. Figure 4.14 shows that the Lubbock

Lake sample has isotopic ratios that are statistically lower than northeastern New Mexico, south Texas, southwestern Oklahoma, and west Kansas. The implication is that Lubbock bison did not traverse at least those four areas. Figure 4.15 shows that the Blackwater Draw sample has ratios that are statistically lower than all of the modern samples. The implication is that the Blackwater Draw bison did not traverse any of the modern sample areas. Figure 4.16 indicates that the Folsom sample has isotopic ratios that are statistically lower than northeastern New Mexico and west Kansas. The implication is that the Folsom bison did not traverse at least those two areas. Figure 4.17 shows that the Lake Theo sample has ratios that are statistically lower than all of the modern samples. The implication is that the Lake Theo bison did not traverse any of the modern sample areas.

T-tests of the prehistoric samples may correlate to the modern distributions of particular elements. An evaluation of this sort can provide information regarding the absence of a prehistoric bison in a particular region sampled by the modern teeth. The prehistoric samples that are markedly different from modern samples can presumably be inferred to have never traversed those areas. For example, B concentrations in the Cooper Middle and Cooper Lower samples indicate that there are no relationships in concentrations among those samples and the modern datasets with the exception of the southwestern Oklahoma B concentrations (Appendix B). One might infer, then, that the two Cooper bison did not traverse those areas sampled; with the potential that the individuals grazed in southwestern Oklahoma sometime during their enamel formation. However, it must be taken into consideration that some of the elements analyzed have similar concentrations in several of the modern sample areas (see

Figures 4.3 through 4.9 and a summary in **Table 4.1**). Some elemental concentrations of the selected minerals are unique to a specific area while others are more heterogeneous across several regions. Using the B example from above, modern samples indicate that a uniquely high concentration exists in southwestern Oklahoma that does not exist for the other samples. Because the Cooper Middle and Lower Kill sample's t-test circles are not significantly different from the southwestern Oklahoma samples it may be inferred that some real relationship exists between these samples.

Table 4.1 Table of selected elements and concentration levels (based on significant differences observed in the t-tests) for modern bison tooth samples.

Element	Concentration	Location
B	High	SW OK
	Middle	S KS
	Low	E KS=NE NM=S TX=SE CO=W KS
Na	High	W KS=SW OK=S TX
	Middle	NE NM=E KS
	Low	S KS, SE CO
Cl	High	W KS=S TX
	Middle	SW OK, SE CO, NE NM, E KS
	Low	S KS
K	High	SW OK
	Middle	NE NM=S KS=S TX=SE CO
	Low	W KS=EKS
Zn	High	S TX=SW OK=W KS
	Low	E KS=NE NM=S KS=SE CO
Sr	High	NE NM=W KS
	Low	E KS=S KS=S TX=SE CO=SW OK
Pb	High	SW OK
	Middle	S TX=SE CO
	Low	E KS=NE NM=S KS=W KS

Notes: = refers to locations that do not have significant elemental differences
, refers to locations that do have significant elemental differences but fall within a range of the data

For the current study, t-tests can provide a glimpse of some of the interrelationships observed in the data matrix, but examining down-tooth records in prehistoric bison requires further investigative techniques that utilize data points throughout the entire tooth (as opposed to averages) to be compared individually to the modern data sets.

PATTERN RECOGNITION AND GROUP EVALUATION

Identifying potential source-related subgroups in the compositional data matrix is the most crucial step in reconstructing bison movement patterns. One approach is to employ noncompositional information (location, time period) as a basis for hypothesizing which teeth can be grouped together. An alternative to this practice is to use numerical pattern-recognition techniques to identify analyzed specimens that are compositionally similar to one another (Neff 2002:18). Ordination or partitioning is an approach for pattern recognition (Bishop and Neff 1989). Ordination includes simple bivariate plots and numerous methods based on eigenvector extraction, the most common of which is principal components analysis (PCA). Partitioning approaches apply various forms of cluster analysis. The current study employs the ordination approach using PCA as it is the most effective method thought to represent the information within a data matrix in spaces of reduced dimensionality, and it is the most commonly used technique in archaeology (Bishop and Neff 1989). Like all ordination techniques, PCA is a tool to condense data. The essence of PCA involves treating data as a geometrical object, and then finding the most informative angle

from which to view the shape. The mathematics underlying PCA were first derived from Peerson (1901) and rediscovered by Hotelling (1933). It became widely adopted by plant ecologists in the 1950s, and remains the ordination technique of first choice for environmental scientists (Shaw 2003:93). PCA provides three useful datasets: projections onto new coordinate axes, the rotations needed to generate each new axis, and the actual information content of each new axis (Shaw 2003:100).

“PCA is based on the extraction of eigenvalues and eigenvectors (also called characteristic roots and characteristic vectors) from a minor product matrix $X'X$ (in R-mode analysis), or major product matrix, XX' (in Q-mode analysis), of a data matrix, X . R-mode analysis is thought of as focusing on variables, whereas Q-mode analysis is thought of as focusing on objects” (Neff 2002:19).

The principal components axes obtained by eigenvector extraction are arranged in order of decreasing amount of variance subsumed (Neff 2002:21). An assumption is that greater interpoint distances may be expected for members of different groups, and different distinct related subgroups will appear as separate point clouds on the object plots of the first several principal components. The view of the data derived from PCA depends on the subset of observations chosen as the basis for the analysis. The observations chosen in the current investigation are the elements, B, Na, Cl, K, Zn, Sr, and Pb.

In a variable space such as that defined by elemental concentrations or log concentrations, groups will be identifiable as regions of relatively high point density

that are separated from other groups by regions of lower point density (Everitt 1993). Evaluation of whether a potential group identified through ordination and pattern recognition may represent a localized source requires that the criteria for judging group coherence be stated formally and explicitly (Neff 2002). Two characteristics define the coherence of groups in multivariate elemental concentration space: location (centroid) and shape (variance-covariance structure). For example, several of the modern bison tooth sample groups plotted in **Figure 4.18** have distinct centroids, but they also differ in how compact they are and how they are oriented when examining the PCA correlation matrix. Plotting the first order principal component against the third order principal component was also done during this study, but no obvious patterns were recognized and they will not be discussed here.

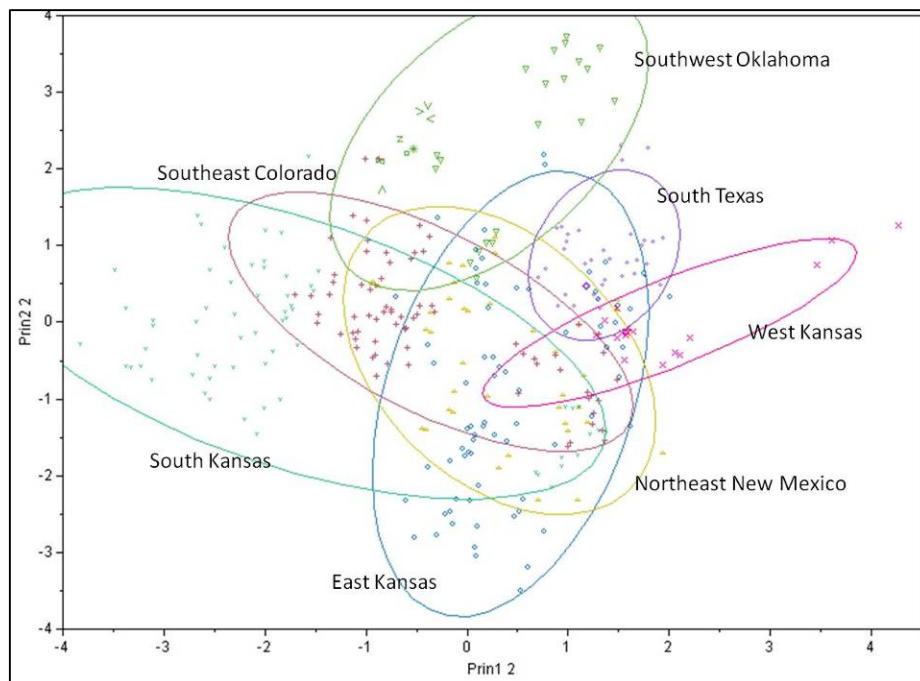

Figure 4.18 PCA plot of modern bison tooth samples and density ellipse ($P=0.90$).

What may be inferred from the PCA plot of modern bison teeth is that a high degree of overlap is observed using the selected elements in this analysis for the various locations. A closer look at the groups revealed by the PCA plot indicates that in several instances two or more groups are present within the density ellipses. These down-tooth points group by individual bison meaning the PCA plot is illustrating a wide range of variation not only geographically, but for tooth specimens from individual bison within the same herd. The south Texas samples, however, group together in a tighter cluster indicating less variation, but these two samples represent P4 premolars from either side of a mandible from a single bison. PCA plots of prehistoric bison samples and modern samples show similar trends (**Figures 4.19 through 4.26**).

Figure 4.19 PCA plot of Jake Bluff and modern bison tooth samples showing density ellipses ($P=0.90$).

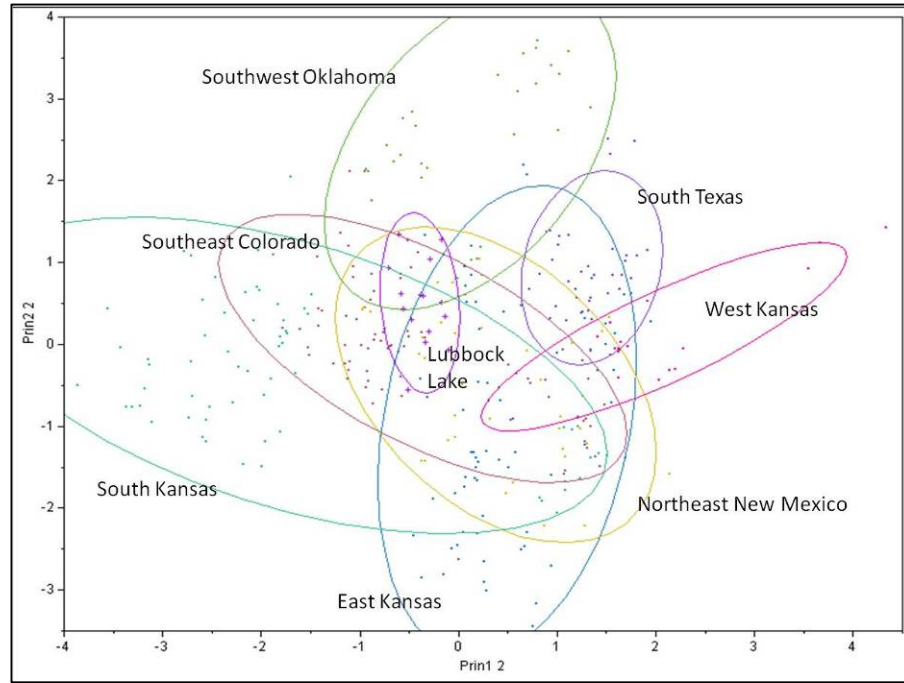

Figure 4.20 PCA plot of Lubbock Lake and modern bison tooth samples showing density ellipses ($P=0.90$).

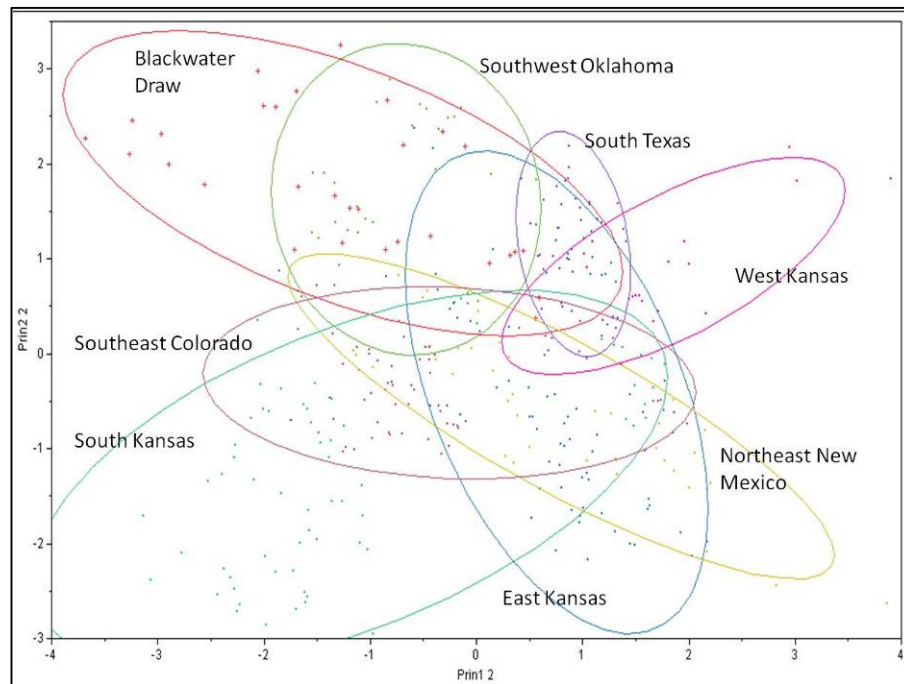

Figure 4.21. PCA plot of Blackwater Draw and modern bison tooth samples showing density ellipses ($P=0.90$).

Figure 4.22. PCA plot of Folsom and modern bison tooth samples showing density ellipses (P=0.90).

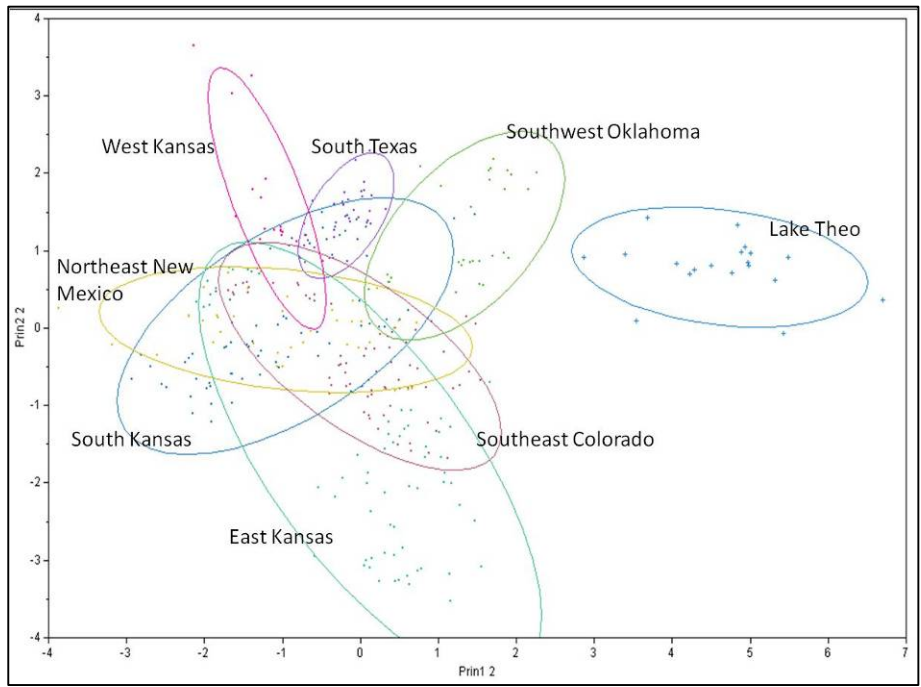

Figure 4.23. PCA plot of Lake Theo and modern bison tooth samples showing density ellipses (P=0.90).

Figure 4.24 PCA plot of Cooper Lower and modern bison tooth samples showing density ellipses ($P=0.90$).

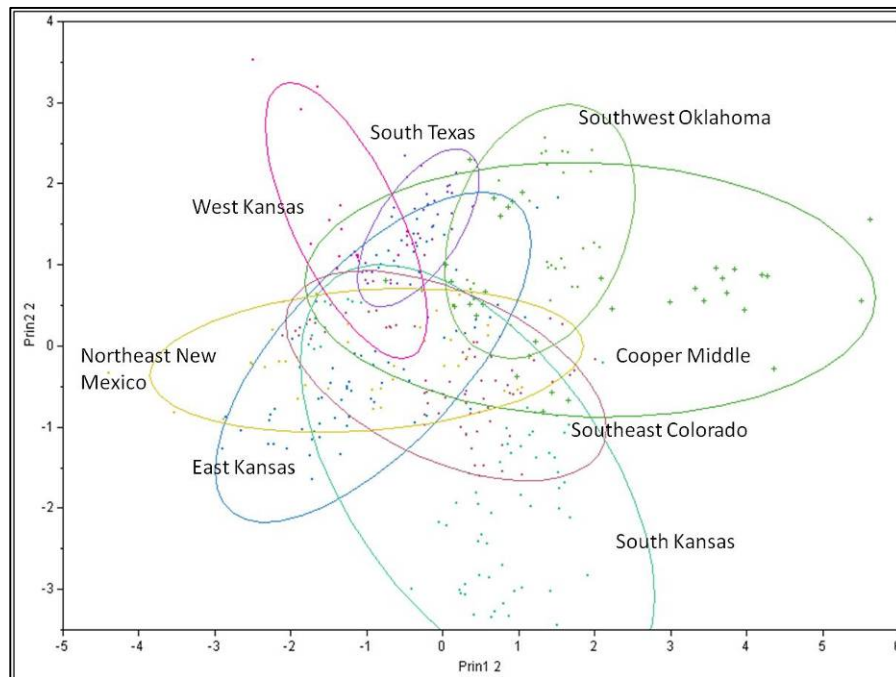

Figure 4.25 PCA plot of Cooper Middle and modern bison tooth samples showing density ellipses ($P=0.90$).

Figure 4.26 PCA plot of Cooper Upper and modern bison tooth samples showing density ellipses ($P=0.90$).

A PCA plot (biplot of the first order principal component to the second order principal component) of the Jake Bluff bison tooth samples group in the middle of plots of the modern samples, and the shape and size of the density ellipse is rounder and smaller than most of the modern samples (**Figure 4.19**). Lake Theo samples are unique in that they group well outside the range of the modern samples, and the density ellipse is similar to those of the modern samples (**Figure 4.23**). Blackwater Draw, Folsom, and each of the Cooper samples are scattered across the entire plot and generally are larger, elongated density ellipses than the modern samples (**Figures 4.21, 4.22, 4.24, 4.25, and 4.26**). Note, however, that within the ellipse of the Cooper Lower samples there are two distinct groups that cluster together by sample (i.e., representative of the two individuals sampled). Jake Bluff most resembles the south

Kansas samples. Lubbock Lake most resembles the northeastern New Mexico, southwestern Oklahoma, and southeast Colorado samples. Blackwater Draw samples most resemble the southwestern Oklahoma samples. The largest cluster in the Folsom plot most resembles the southwestern Oklahoma samples. Lake Theo is unlike any of the modern plots. Cooper Lower and Cooper Middle samples most resemble southwestern Oklahoma samples. The largest cluster of Cooper Upper samples most resembles northeastern New Mexico samples.

These biplots help identify potential patterns as discussed above but they do not reveal information about the down-tooth records of prehistoric teeth. Rather, we are only supplied with a comparison of modern and prehistoric sample averages. In order to discuss prehistoric bison movement – keeping in mind those lessons learned above regarding potential variation within a single tooth and variation within a herd – we need to examine modern tooth averages and point-to-point trends observed in the prehistoric samples. To understand how elemental compositions changed down the prehistoric tooth, and how these changes may be related to specific nodes on the landscape observed in averages of our modern sample data, we can plot each point down the tooth against the first order principal component (which is a representation of the selected elements for several samples for several locations). **Figures 4.27 through 4.34** illustrate the kinds of trends in the prehistoric sample data as they relate to specific geographic locations.

Figure 4.27 Plot of Jake Bluff down-tooth record and modern bison tooth samples (mean P=0.90) to the first order principal component.

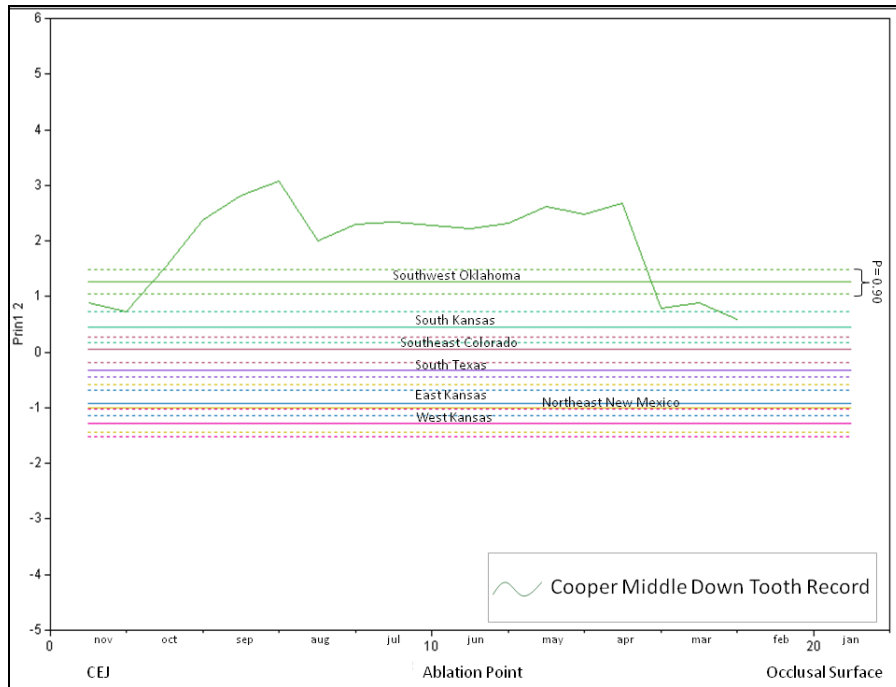

Figure 4.33 Plot of Cooper Middle down-tooth record and modern bison tooth samples (mean $P=0.90$) to the first order principal component.

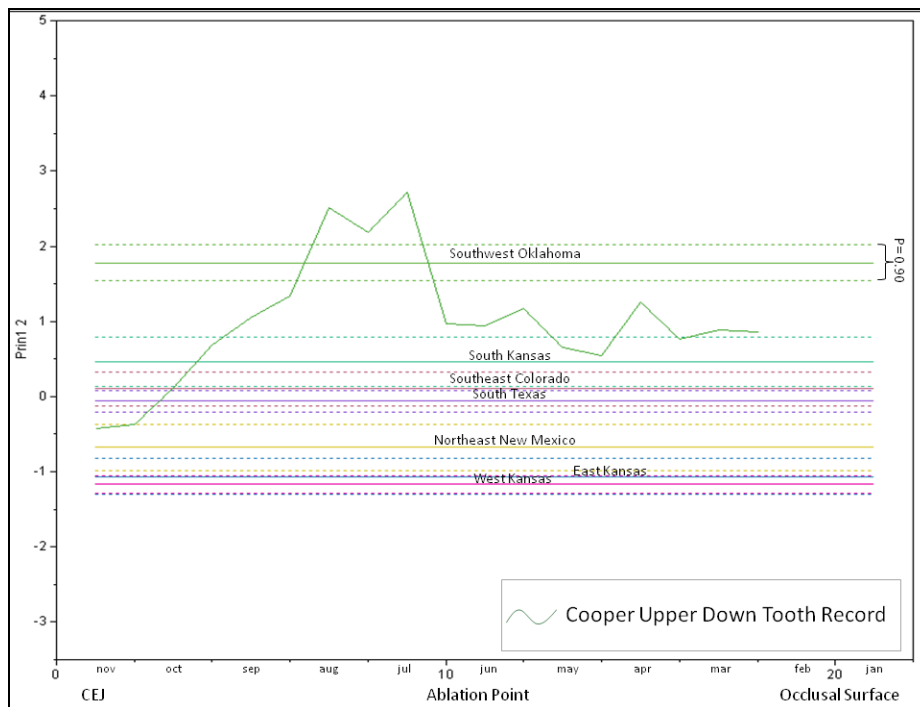

Figure 4.34 Plot of Cooper Upper down-tooth record and modern bison tooth samples (mean $P=0.90$) to the first order principal component.

Trends observed in the plots above are numerous. Many of the down-tooth points in the Jake Bluff samples resemble those of the modern south Kansas samples (**Figure 4.27**). At the onset of enamel mineralization, the individuals in the Jake Bluff bison assemblage grazed in a location approximating the elemental composition to that of south Kansas. By the spring and during the summer months, the bison were grazing in an area that does not parallel any of the areas sampled by this study. During the fall, bison were back consuming grasses in an area with a similar mineral composition to that of south Kansas. While we cannot conclusively say that bison at the Jake Bluff site traveled to south Kansas because we do not know the elemental composition of the Jake Bluff site proper, we can observe a few items of interest. First, we know the Jake Bluff bison did not travel during the early spring and through the mid- to late fall to any of the modern locations sampled by this study except for perhaps south Kansas. Since we know Folsom-age hunters may have been attempting to predict the movement of bison at the Jake Bluff site (as hunters will naturally do) in an effort to procure large herds during the late summer/early fall, the data may indicate that the Jake Bluff locality itself is similar in elemental content to a location we did not sample during this study. If that is indeed the case, the Cooper bison sampled in this study should also not have data points within known sample areas for the late summer/early fall months. Finally, it appears from the data that Jake Bluff bison did not move far, or at least for an extended period, from the area where they met their demise.

The Lubbock Lake samples indicate very little down-tooth variation, and have an elemental composition very much like the modern bison samples from southeastern Colorado (**Figure 4.28**). It does not appear much mobility is evident in the bison sampled from Lubbock Lake, and it is quite likely that the Lubbock Lake locality has an elemental composition similar to that found in southeastern Colorado.

The Blackwater Draw samples indicate a high degree of variability and for the first several months of enamel mineralization, uptake of the elements sampled did not occur in any of our modern sample areas (**Figure 4.29**). By the summer, the bison at Blackwater Draw appear to be visiting locations with elemental composition similar to that of south Kansas and then on to areas similar to southwestern Oklahoma during the months humans would have been attempting to find large herds on the Southern Plains.

The Folsom site samples indicate a high degree of variability and for the first several months of enamel mineralization, uptake of the elements sampled for occurred near the 90 percent confidence interval for west Kansas (**Figure 4.30**). However, it appears there are not enough data to understand the grazing location for these early months of amelogenesis. During the fall, the bison were grazing an area similar to that of southwestern Oklahoma, and moving on to an area with similar elemental content to that of west Kansas by the winter months.

Elemental composition trends observed in the Lake Theo sample are difficult to interpret as they are highly erratic, and none of the down-tooth points fall within the known modern tooth sample areas (**Figure 4.31**). Future studies should focus on

obtaining information about the elemental composition of areas near the Lake Theo site.

At first glance, the Cooper Lower samples appear to show movement across the board from northeastern New Mexico to southeastern Colorado to southwestern Oklahoma to south Texas to west Kansas (**Figure 4.32**). Looking closer at the actual data points, many do not fall within known modern source locality points. Specifically, and as alluded to above with the Jake Bluff bison discussion, evidence for fall movement are not within the range of our known modern sample areas supporting the hypothesis that the Jake Bluff/Cooper Lower site area has a relatively different elemental structure than what was sampled for from modern bison used in this study.

The Cooper Middle samples show similarities to south Kansas very early in enamel mineralization, but the remaining points have no relationships to the modern samples. The Cooper Lower samples reflect this sort of trend as well with a couple of points early and late during amelogenesis having elemental composition similar to that of south Kansas, and the rest indicating no relationships with the remaining data matrix.

General observations for the down-tooth plots include a trend toward less variability in the data for earlier dated sites like Jake Bluff and Lubbock Lake, whereas the middle and later Folsom-age sites (Cooper, Folsom, Blackwater Draw, and Lake Theo) all have highly varied down-tooth patterns. One may infer from the limited data that bison became more mobile over time through the Folsom Period. Also observed are relatively large spring and fall month spikes in the down-tooth record for bison tooth samples with greater variability (Cooper, Folsom, Blackwater Draw,

and Lake Theo). This type of exaggerated elemental signal suggests that these bison were more mobile during the spring and fall, which is consistent with known modern bison herd movement (McHugh 1972).

CONCLUSIONS

This chapter described some of the quantitative tools that proved useful in chemistry-based provenance research. Once data are collected, the general course of investigation proceeds from data transformation to pattern recognition to group evaluation. In practice, there is feedback between the stages. Further, each part of the analysis needs to be tailored to the specific conditions of the environmental and diagenetic properties of the samples analyzed. Quantitative techniques do not relieve us of having to define potential problems with our raw data, our research design, and sampling techniques. The techniques and groups evaluated and discussed in this chapter indicate that some bison herds in the Southern Plains moved significantly more than others. The discussion presented in the following chapter shows how the patterns described above can be combined in various ways to address specific questions about Folsom-age bison movement. From those inferences, we can begin to discuss how people would have negotiated potential patterning of bison movement.

CHAPTER 5: MODELING MOVEMENTS OF THE GIANT BISON AND FOLSOM-AGED HUNTER-GATHERERS

Coupling the information presented in Chapter 4 with the archaeological assemblages at the sites examined for this study reveals insights into the mobility strategies of Folsom-age people. Further, I can comment on the potential communal efforts involved with locating and procuring bison on the Southern Plains. This chapter is primarily concerned with first identifying if Folsom-age bison were moving and where they went, and from that information addressing how humans were moving and organized at several kill loci.

The impetus for the discussion in this chapter stems from Bement (1999, 2003). He presents a suite of data supporting a dichotomy between the size and seasonality of bison kills sites as a result of population aggregation in the late summer and early fall for large-scale kills, and a dispersed pattern with small bison kills during all other seasons. Although a direct link can be established between specific sites on the Southern Plains, suggesting a round of movement of a single human group, if a dichotomy exists, then there should be redundancy in the archaeological record.

When the Folsom-age sites used in this study are compared, links between large kills and a late summer/early fall seasonality, and an association of small kills to winter/spring seasonality are apparent. Location, butchery, landform, seasonal context, and lithic assemblage information from the sites examined during this study reveals a number of patterns regarding bison and human movement (**Table 5.1**).

Bison kills at Lubbock Lake and Blackwater Draw are dominated by Edwards Plateau chert. Kills farther north and east, and those that are larger kills, have Edwards chert projectile points, but some Alibates tools as well. Animal processing techniques vary according to setting, seasonality, bison mobility, and size of kill. The larger late summer/early fall kills have more articulation of the carcasses (Bement 1997), whereas smaller winter/spring kills were more heavily processed (Johnson 1987). Also, a correlation exists between bison herds with less mobility, and sites with heavier processing.

Table 4.1 Table of site attributes for locales examined by the study.

Site	MNI	Season	Stone Types	Butchery	Landform	Stage of Points Use	Bison Mobility
Jake Bluff	22	Fall	Alibates, Quartzite	Mixed	Gully	75% Reworked	Residential
Cooper Lower	20	Late Summer/Early Fall	Edwards, Alibates	Light	Gully	20% Reworked	Mobile
Lubbock Lake	3	Spring	Edwards, Alibates	Heavy	Pond	68% Reworked	Residential
Cooper Middle	29	Late Summer/Early Fall	Edwards, Alibates, Unknown	Light	Gully	63% Reworked	Mobile
Cooper Upper	29	Late Summer/Early Fall	Edwards, Alibates, Niobrara	Light	Gully	50% Reworked	Mobile
Folsom	32	Fall	Edwards, Alibates, Tecovas, Unknown	Mixed	Gully	20% Reworked	Mobile
Blackwater Draw	2 - 5		Edwards, Alibates, Niobrara	Heavy	Pond	74% Reworked	Mobile
Lake Theo	12	Fall	Edwards, Alibates, Tecovas, Unknown				Mobile

Bement (1999:160; 2003) asks why this dichotomy exists among bison herds with less mobility and sites with heavier processing, and suggests the variation is tied to bison aggregation and movement cycles. Large hunts of numerous species in various regions of the world correspond to cyclical animal aggregation and migration schedules, so why wouldn't the same be true of Folsom-age predators and their prey? Developing an understanding of the annual cycle of prey species to interpret the decisions of hunters has been a dominant theme in Plains archaeology (Frison 1970, 1987, 1991; Wheat 1972), and is the central focus of the current study.

Generally, the annual cycle of past bison herds is inferred from ethnographic data or movements of modern “free-ranging” herds. Mobility patterns are one of the most intensively investigated aspects of bison behavior (Krasinska et al. 2000; Roe 1951; Seton 1910). All grazing animals deplete the available forage in the area in which they live and therefore must move when forage becomes scarce in their local area. The key questions that most interest researchers concerning bison mobility are: How often do they move? How far do they move? What factors influence this mobility?

BISON MOVEMENT

Early historic accounts (e.g., Allen 1876; Arthur 1975; Roe 1951; Seton 1910) argued that bison seasonally migrated hundreds or thousands of miles. Allen (1876:59–61) reported,

“I have...been assured by former agents of the American Fur Company that before the great overland emigrations to California...divided the buffalo into two bands, the buffaloes that were found in summer on the plains of Saskatchewan and the Red River of the North spent winter in Texas.”

Later historians, though discounting these very long migrations, nonetheless steadfastly argued that bison seasonally moved hundreds of miles. Seton (1910:266) stated, “I conclude with Hornaday that the buffalo did migrate 300 to 400 miles northward in the spring, and as far southward again in the autumn.” These kinds of statements dominate most ethnohistoric records (see Bamforth 1987; Hornaday 1889; Roe 1951; Soper 1941).

Researchers have questioned these early ethnohistoric accounts. Roe (1951:78) concluded that the idea of long bison migrations is based on analogies to the cattle drives of the late nineteenth century in which domestic cattle were annually moved vast distances. As Roe (1951:77) stated, “a careful study...reveals how flimsy is much of the evidence upon which various forms of the migration argument are based.” Several researchers have outlined problems with these early models of long-distance bison mobility (Bamforth 1987; Hanson 1984; Roe 1951). First, no definitive evidence exists that an individual bison can walk 1,400 miles from Texas to southern Canada in a single year. Second, none of these models explain the impetus for such a long-distance migration. As discussed in Chapter 1, there are various reasons animals move, and these reasons are not clear in the ethnographic accounts. More recently, the focus of research has switched from the distance bison may move to the ecological factors that cause bison mobility.

Based on the definitions outlined by Baker (1978), bison are neither nomadic (i.e., having no apparent fixed pattern of direction) nor long-distance movers (Lott 1991). There are several reasons why bison move, including the search for food and water, search for other bison, and escape from danger or uncomfortable conditions (e.g., cold temperatures, snowfall, insects, and predators) (Hanson 1984; Krasinska et al. 2000; Lott 1991; Morgan 1980; Roe 1951; Senft et al. 1987). Random events, such as inclement weather or attacks by predators (including humans) also cause bison to take flight. But these moves usually occur over short distances, usually less than 10 km (Bamforth 1988).

Modern bison also appear to have predictable movements to the same geographic location. A multi-year tracking study of European bison, for example, saw a high proportion of bison returning to the same summer and winter ranges over multiple consecutive years (Krasinka et al. 2000). Similarly, a number of accounts suggest that Plains and wood bison repeatedly move back and forth between the same summer and winter forager areas (Lott 1991; Meagher 1973; Soper 1941). Baker (1978) identified this type of movement as “seasonal latitudinal return migrations” (see Lott 1991). At Yellowstone National Park, McHugh (1958:13) observed that the Lamar Herd bison move approximately 25 miles from the meadows at 8,000–9,000 feet to the lower Lamar Valley at 6,000 feet during the winter. In May or June the bison return to the higher elevations. Soper (1941:380) observed that for the herds at Wood Bison National Park, Canada, bison move from the plains of the Western Slave River in the spring to the uplands of the Alberta Plateau. In the fall, bison return to the plains. The bison at Henry Mountain, Utah, also move into their winter range in September and return to their summer range (approximately 15 km away) in May and June (Nelson 1965:24–29). Recent isotopic analyses (e.g., strontium, stable carbon) of archaeological bison remains suggest that prehistoric bison, like their modern counterparts, probably did not range over vast territories, but instead were restricted to relatively small seasonal and annual patches (Widga 2006a, 2006b).

Epp and Dyck’s (2002) research regarding behavioral ecology and its implications for bison mobility and numbers has led to the identification of two distinct, but not mutually exclusive, bison herd populations: resident and migrant herds. Their research shows that behavioral ecological views regarding bison numbers and

population dynamics should be reassessed on three bases: (1) there were often two discrete populations of bison species within any area at any given time; (2) the migratory population moved between two distinct home ranges; and (3) migrant herds tended to have larger home ranges vastly outnumbering resident herds, often by 4:1 or more (Epp and Dyck 2002:324,325).

So were Folsom-aged bison populations comprised of both resident and migrant bison? This study furthers the understanding of past bison movement through examination of the down-tooth distribution of B, Na, Cl, K, Zn, Sr87/Sr86, and Pb. While I identified intra-tooth variation of bison within the same herd, elemental signatures for modern herds approximate the variability of prehistoric samples in some cases, and diagenetic effects were observed in this study, patterns in the data emerged that indicate a presence of both resident and migratory herds during the Folsom Period. Figures 4.27 through 4.34 indicate a range of variability among the prehistoric bison tooth samples with a trend toward the earlier dated sites and spring kills being comprised of less mobile bison (**Figure 5.1**). The Jake Bluff bison that were examined in this study appear to have either not moved a great distance, not moved away from the Jake Bluff locale for very long, and/or remained in a homogenous geologic environment throughout the year the P4 premolar enamel mineralized. The Lubbock Lake individuals reflect this trend as well. Remaining prehistoric samples showed a high degree of down-tooth variation with spikes in the data during the spring and fall, which is consistent with the behavior of known herds in Yellowstone that have greater flexibility in their movement patterns.

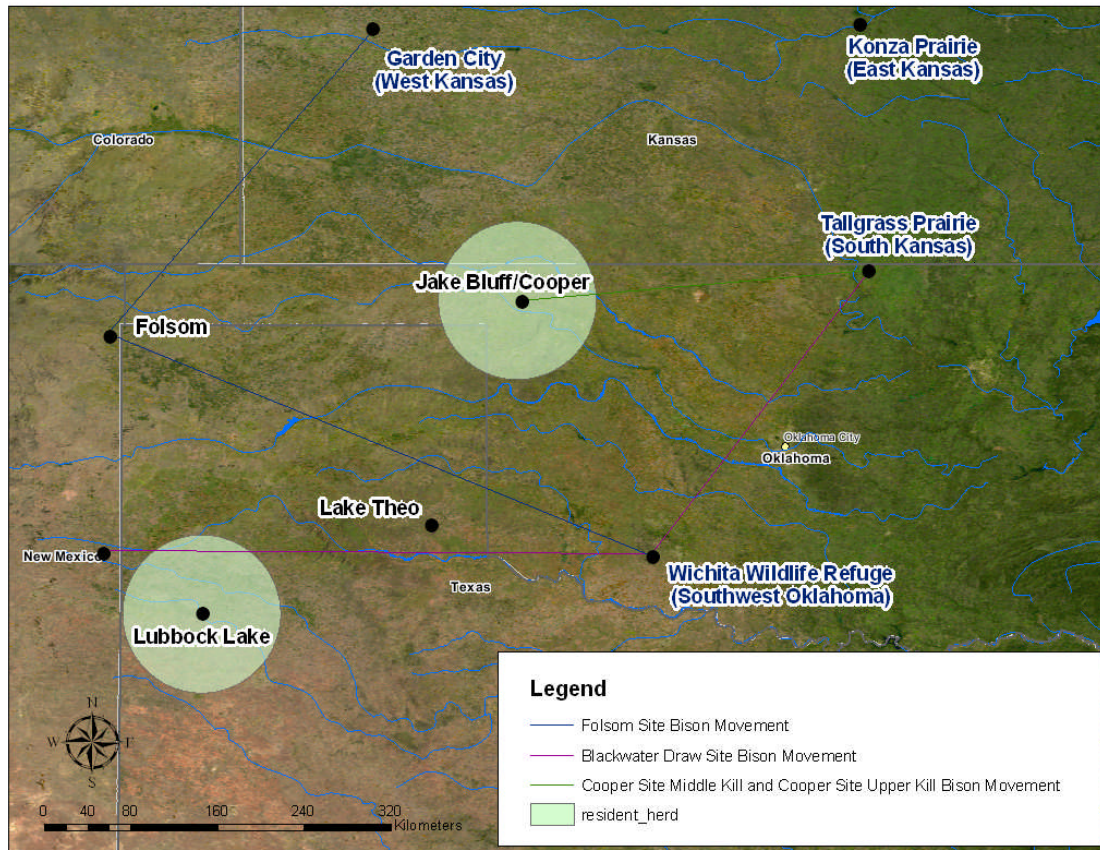

Figure 5.1 Locations of residential herds at older and spring season Folsom-age sites, and linear movement of bison from elemental analysis for younger Folsom-age sites.

With the limited data we have on change through time during the Folsom Period on the Southern Plains, one may argue that more residential herds were present earlier in the period (11,000 – 10,500 BP), while migratory herds dominated the later period sites (10,500 – 10,400 BP). Until further evidence are retrieved, however, we cannot yet know the distribution of residential and migratory herds through time and space during the Folsom Period.

Determining directional movement of bison is possible even with the limited number of locations sampled by this study, and seasonal movement patterns emerge from the data that provide insights into potential latitudinal bison movement. Patterns of similar movement are observed in the findings (Figures 4.33 and 4.34) for the Cooper Middle and Cooper Upper samples. Movement from an area similar in elemental composition to that of south Kansas in the spring to an unknown area in the late summer and early fall, and then a return in the winter to the same mineral environment grazed during the spring is apparent in both assemblages (**Figure 5.2**). It is not surprising, too, that these kills are only separated by less than one human generation in time. This kind of mobility is consistent with known bison behavior.

The Blackwater Draw and Folsom bison samples show similar cyclical patterns in their movement. The Blackwater Draw bison indicate movement from a south Kansas-type elemental environment during the late spring to southwestern Oklahoma during the fall and a return to south Kansas in the winter (**Figure 5.3**). Elemental values at the top of the tooth are markedly different from the rest of the down-tooth record and may be an artifact of tooth wear of the sample. Folsom bison moved from an area exhibiting an elemental composition similar to that of west Kansas to southwestern Oklahoma in the fall with a return to west Kansas in the winter (**Figure 5.4**). At the very least – and because elemental composition of the Llano Estacado is assumed to be different from that of the surrounding Central Plains to the north and Rolling Hills to the east – the movement evidenced from these four locales suggests an east to west movement, from the Rolling Hills to the Llano Estacado, during the spring through the fall and a return to the Rolling Hills to winter.

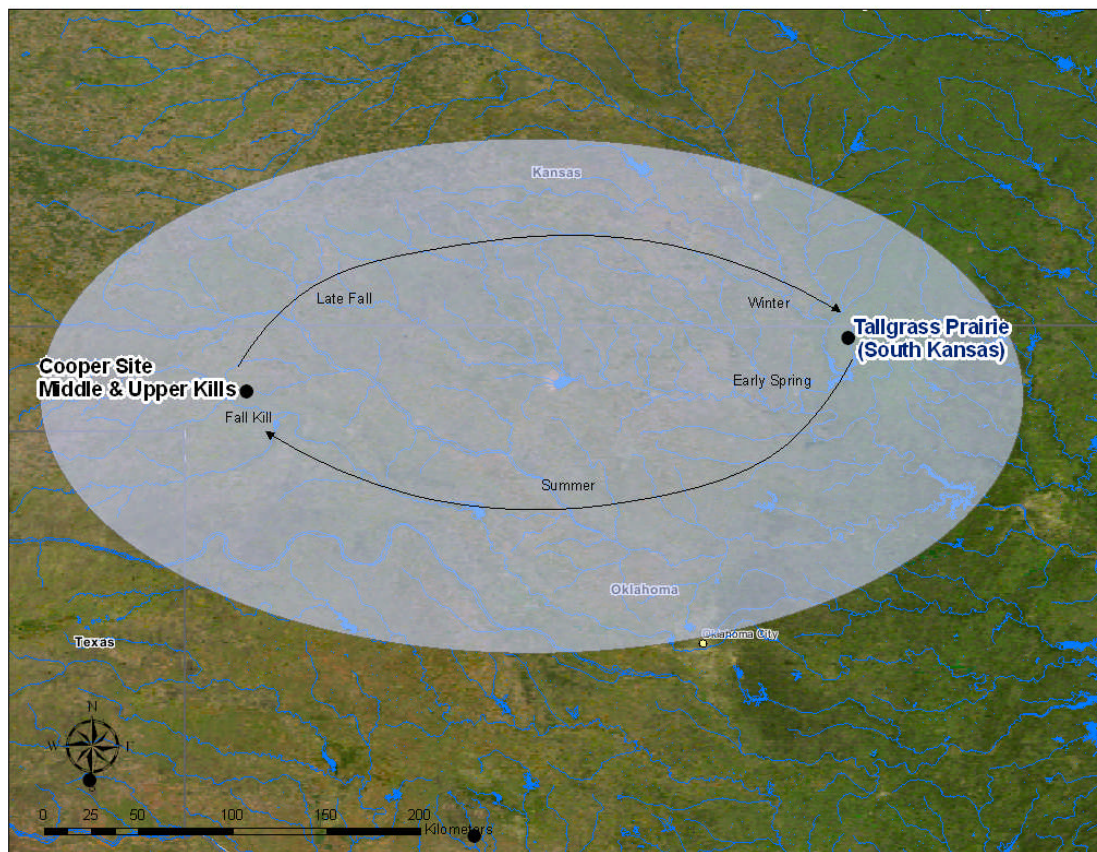

Figure 5.2 Cooper Site Middle and Upper Kill inferred bison movement from elemental analysis.

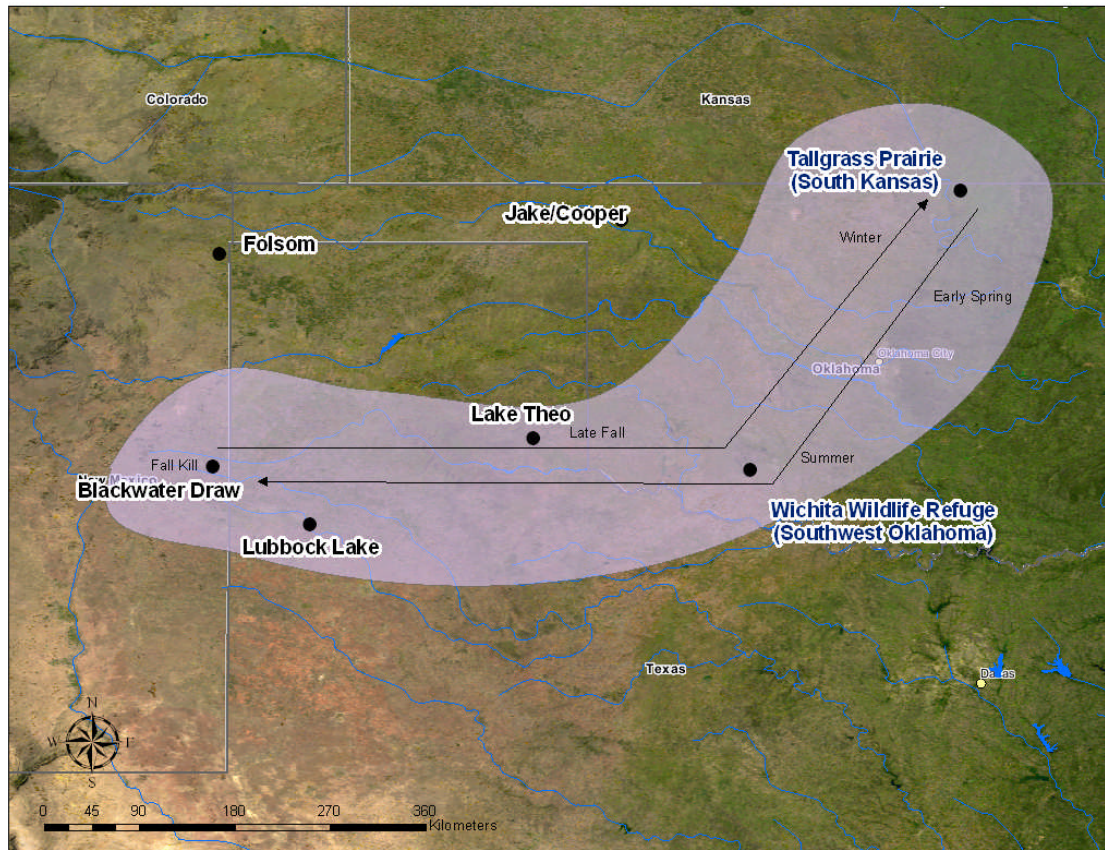

Figure 5.3 Blackwater Draw Site inferred bison movement from elemental analysis.

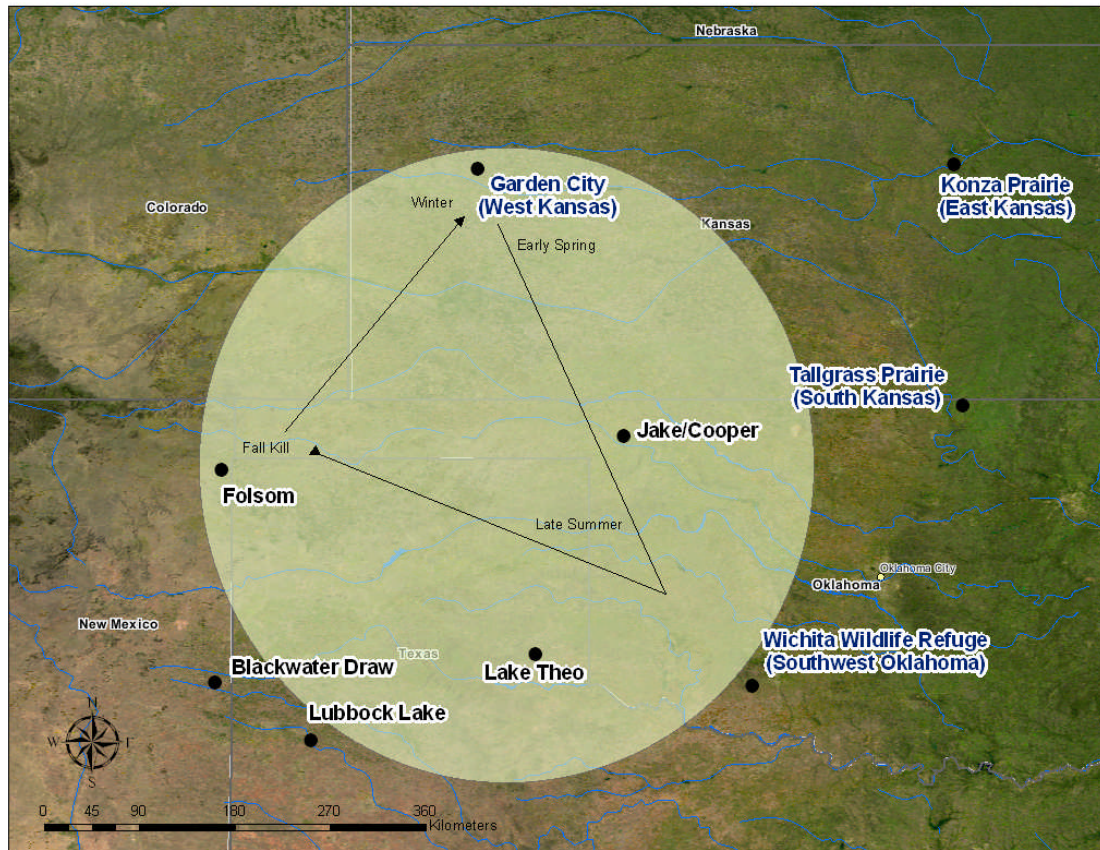

Figure 5.4 Folsom Site inferred bison movement from elemental analysis.

Figures 5.1 through 5.4 illustrate a pattern of movement on and off of the Llano Estacado in accordance with changing seasons. The elemental analysis provides a window into one year of movement and it appears that teeth representing migratory animals have similar elemental concentrations at the crown and CEJ. In other words, the bison grazed similar areas when amelogenesis began as they did when mineralization of enamel was complete indicating a circular movement pattern. Additionally, bison herds from various Folsom-age archaeological sites seemingly had overlapping ranges, or were potentially a single moving population.

HUMAN SUBSISTENCE AND MOBILITY STRATEGY

This study is not the only one to suggest the exploitation of migratory and residential bison herds by humans. Epp and Dyck (2002:332-334) offer an optimal foraging model that suggests people continuously exploited resident bison populations and seasonally exploited migrant bison populations in order to have an enormous supply of a high-quality protein resource and to ensure resident and migrant bison herd numbers. This subsistence strategy had several important implications for both humans and bison because the combined use of these herds would have ensured that the people had almost constant access to bison. As well, it ensured that neither the resident nor the migrant population was eliminated. Consequently, hunting both resident and migrant bison populations was an optimal subsistence strategy.

Anthropologists have long been interested in subsistence strategies; thus, applying evolutionary ecology theory to hunter-gatherer subsistence practices has obvious relevance (see Chapter 2). Models that can operationalize optimal diet breadth and group formation concepts have a great likelihood of increasing our understanding of foraging and human settlement patterns. When testing for optimal solutions, several active selective forces or behavioral attributes of a group of people can be measured. Decisions that are made about how, when, and where a group of people direct their procurement activities are variables that can be defined and measured by analyzing Folsom-age bison teeth.

Applying elemental analysis data to this model shows that these optimal decisions are identifiable in the archaeological record. People will adapt and respond to their

physical environment by exploiting a high-quality protein resource such as bison on a yearly basis by hunting both migrant and resident bison herds.

Numerous studies have alluded to the need to determine the behaviors of Folsom-age bison on the Southern Plains (Bement 1999, 2003; Hofman 1994) so that a correlation between such movement and the behaviors of humans (as evidenced through the locations of sites, the lithics identified on those sites, and the processing strategies observed at those sites) can be made. Questions about the directionality of human movement (Hofman 1991), the relationship between Folsom-age sites to determine regional variation (Amick 1996), the scale of human movement, and the potential for aggregations/communal efforts to hunt bison have all used various lines of evidence to support various answers to these questions.

Elemental data presented above illustrates an apparent east-to-west movement of migratory bison herds and the presence of residential herds during the Folsom Period. Folsom groups on the Southern Plains exhibit a close relationship to those areas where they obtained lithic raw materials. Humans at this time quite obviously obtained raw materials for the tools they needed in Texas and successfully hunted bison on the Llano Estacado adjacent to these toolstone sources. What then was the impetus drawing these same individuals to the periphery of the Llano Estacado hundreds of kilometers away from a reliable lithic acquisition area? The answer is that bison were nearly as reliable a resource as the knappable stone they used to dispatch and process the animals. Hunters operating in an environment where residential bison herds were present in various ecological patches, and where

migratory bison regularly wintered on the Rolling Hills, moved west to the Llano Estacado through the summer and fall, and returned to the Rolling Hills again for the following winter would have little trouble predicting where and when they could organize their own movement to best take advantage of seasonally available resources.

I submit that Folsom hunters-gatherers whose toolkits were composed primarily of Alibates spent much of the year on the Llano Estacado taking advantage of the numerous available resources, and moved to the landform's peripheries during the fall bison rut (**Figure 5.5**). Small bison herds or individual bison on the Llano Estacado that were dispatched in the spring would be difficult to hunt if they were undertaking their spring migration. A more likely scenario is one where residential herds or individual bison are dispatched, because their whereabouts would be predictable during the spring. Anticipating large, but temporarily occupied bison herds during the late summer rut near or on the dissected peripheries of the Llano Estacado would be feasible and the best time and place to successfully hunt, trap, and dispatch large groups of bison. Additionally, these locations would be the best places to meet groups of people moving north from the Edwards Plateau source area.

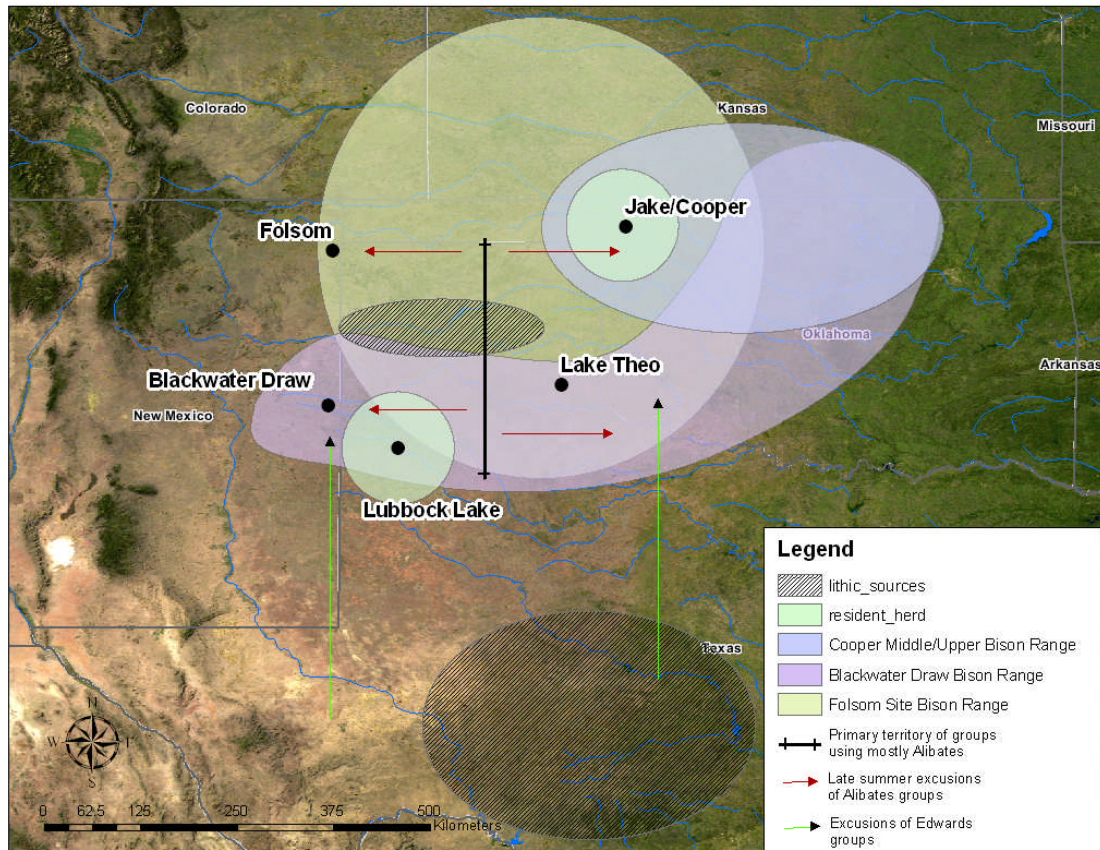

Figure 5.5 Folsom-aged hunter-gatherer movement in relation to *Bison antiquus* movement.

Why though, if residential herds were present during the Folsom Period on the Southern Plains, would it be necessary to move so far away from their seemingly preferred lithic acquisition locales? Two reasons come to mind: one is general conservation of the residential herds, and the other is to meet with other groups for the purposes of conducting social activities. As with other human colonization sequences, the first arrivals take the best locations and hang on to them. As the best locations become occupied and the resources become patchy during Folsom times,

strategies for obtaining resources must change. Human groups using Alibates developed seasonal rounds in the middle of a bison-rich ecosystem, and Edwards Plateau groups developed movement to interact with Alibates groups and procure a highly valuable resource in an efficient manner. The Edwards group or groups may have been small bands who needed to gather with other bands seasonally to make large bison kills, trade, and exchange marriage partners. The former reason for communal gatherings is the focus of the discussion below.

Communal hunting is part of a larger pattern of predation in which the strategy is to acquire an adequate amount of animal resources for a group larger than those participating in the hunt in as efficient a manner as possible. In this study, Driver's (1990) definition of communal hunting is used. He characterized communal hunting by the following traits (Driver 1990:12):

1. Participation by more than two hunters (usually many more than this).
2. Active cooperation between hunters such that they work together, as opposed to passive cooperation in which hunters agree not to interfere with each other's activities.
3. A system of hunting that requires all hunters to participate in a previously conceived plan.

For large game animals, such as bison, habitat, migration route, population density, meat, fat, and hide quality vary seasonally (Driver 1990:13). Consequently, incorporating information about certain environmental features and the adaptive

strategies people use to optimize their foraging practices can help reveal variation in social behavior as evidence by the current study.

The characteristics of the animal often will determine the hunting strategy adopted. Mobile, clumped prey, such as migratory bison, require an aggregated group strategy, whereas stable, evenly distributed prey, such as deer, require that the hunters be dispersed (Winterhalder 1981a:31). Driver (1990:23) maintains that “The widespread use of communal hunting in association with concentrated groups of animals suggests that the relative ease of killing may have been an important factor.” When considering how bison herd composition can vary according to the patchiness of a particular region, the optimal goal of search and handling time efficiency may lead to behavior that may not make the best use of labor efficiency. In fact, labor productivity may not be important when considering time efficiency if the goal is to take advantage of a seasonally available resource that may require a group of people to expend large amounts of labor for a short period of time (Jochim 1981:52). Due to the mobile nature of some bison, pursuit distances probably fluctuated on a seasonal basis, causing hunting groups to travel farther in order to obtain this highly sought resource. On the other hand, periods of prey aggregation may be highly predictable for migratory herd animals. In which case, search times would be reduced, particularly if hunters employed communal hunting techniques (Driver 1990:27). The evidence presented in the current study suggests a predictable pattern of bison behavior, and it can be inferred that the species was an excellent candidate for employing communal hunting techniques.

Hunter-gatherers are selective about which animal body parts are transported from the kill site back to the residential camp or village and the transport distance is an important variable in determining how many bones are transported (Metcalf and Barlow 1992:341). As a result, transport and processing decisions vary according to the animal species being exploited. Increasing the use of an aggregate resource such as bison would increase protein yields for any group of people. But, considering the large size of bison, people would also have to increase their return rate costs due to increased transport costs. Transport costs include prey size and distance from the kill site to the camp and the proportion of elements transported. Undoubtedly, in regards to hunting bison, search and handling time costs would increase given that the farther people go to hunt bison the greater the amount of field processing required in order to average out the costs of return travel due to the increased load size. In order to decrease transport costs, hunters butchered bison at kill sites and then made decisions regarding which parts of the animal would be transported back to the camp. For Folsom hunter-gatherers who were highly mobile during the fall months on the Southern High Plains, presumably they were not planning to haul their meat long distances as it would be impractical to carry such an enormous load.

It is generally accepted that Paleoindian population density was very low and the residential mobility was high, at least seasonally. Living in a very large, relatively unbound landscape, Folsom people's need for information exchange, economic cooperation, mates, group rituals or ceremonies, and access to trade goods was likely at a premium. Archaeologists have long assumed that Paleoindians satisfied these needs through periodic and temporary aggregations (i.e., fusion) of different groups

(e.g., Bamforth 1988, 1991; Greiser 1985; Wilmsen and Roberts 1978), and Bamforth (1991) suggested Paleoindian social aggregations were tied to communal bison hunts.

Hofman (1994) is critical of any perspective that argues for aggregations as a single type of site or event. He suggests that Paleoindian demography, subsistence, and land-use patterns may not fit any existing model as to why hunter-gatherer groups aggregate. Instead, he proposes that hunter-gatherer aggregations were a mechanism by which different groups could solve problems that were beyond the capacities of any single group, such as finding spouses, conducting necessary spiritual rituals, and gaining information about very large geographic regions (Hofman 1994:342). As a result, he sees aggregations arising for a wide variety of reasons and under diverse conditions. Therefore, multiple archaeological expressions of aggregation localities may exist depending on when, where, and why the fusion of different groups occurred. Hill (2007) believes it unlikely that social aggregations would have involved large communal hunts because (1) they would have occurred in landscapes with no major landscape features (Plains), (2) very few additional resources would have been available (high risk), (3) there may be no correlation between the number of bison killed and the number of people it would take to dispatch and process them (see also Hofman 1994), and (4) there is little evidence (lack of lithic and camp debris) for large number of people coming together.

One may infer from the findings presented in the current study that aggregations for the purposes of social activity provide an excellent opportunity to hunt large herds of bison in a landscape that provides numerous traps and landmarks for such an

endeavor. The predictable nature of bison, residential herds coupled with migratory herds, with regular and scientifically testable movement of bison, has been known by Plains bison hunters for at least 11,000 years. Further, the evidence for a large number of people coming together may be found at the large kill sites themselves. For example, the middle level of the Cooper site contained at least 29 *Bison antiquus*. The approximate meat weight yield from a modern cow bison using a Cooper-type butchering strategy yields approximately 61.7 kg or about half of the total meat weight of the animal (Johnson and Bement 2009:1445). Even a conservative measure (using modern cow bison size as opposed to *Bison antiquus*) of the total meat yield during the Cooper middle kill would be 1,790 kg (about 4,000 lbs.). Presumably, human groups present at or near the Cooper locale, even while operating in a highly mobile manner, would not likely have packed up that much meat and immediately hauled it back to the Llano Estacado. It would have taken several groups of people several trips from kill to a campsite far enough away to avoid the pleasure of 29 rotting bison carcasses and the scavengers that accompany decomposition. Furthermore, a few good hunters would have little reason to process over 4,000 lbs. of meat.

CHAPTER 6: WHAT HAVE WE LEARNED?

This research has supported a number of methodological and theoretical questions. The first is the method of laser ablation of bison teeth to examine spatial and temporal dietary changes. Extracting down-tooth elemental compositions from bison teeth as a method of determining diet and mobility has proven successful using laser ablation techniques and principal component analysis. More closely examining each element observed in the tooth enamel to better understand the biochemical and metabolic processes (how elements move through geologic, soil, vegetation, and animal systems) will only refine the technique. More modern samples will provide a better elemental map of the Great Plains, and more prehistoric samples will further our efforts to understand past human movement. More Jake Bluff and Lubbock Lake samples would provide better data to confirm the presence of resident herds. Examining modern bison teeth from Yellowstone (greater flexibility in their movement) may reveal similar spikes in the down-tooth record reflecting greater movement in the spring and fall.

Second, the results of elemental analysis using laser ablation indicate that Folsom-age bison were indeed moving, albeit not all of them. The evidence presented in this study suggests a latitudinal movement of bison on and off the southern High Plains according to seasonal changes during the Folsom Period. I posit that the manner in which humans located bison on the Southern Plains and organized their movement strategies (aggregation and dispersal) to hunt bison took advantage of the locations of bison across the landscape during different times of the year. Further, Folsom hunters

structured their settlement in a way whereby residential mobility was low throughout much of the year, but high during the fall when moving to the periphery of their territory on the Southern Plains was advantageous for meeting other groups and procuring large numbers of bison. Herd composition and mobility always affects the amounts and kinds of mobility for humans, which is why the relationship between Plains hunter-gatherers and the bison they hunted remained unchanged for 11,000 years.

The Folsom Period may be the first time in North America that those institutions of territoriality are expressed, and may warrant a look at Folsom groups as *foci* (perhaps the Folsom Alibates Focus for the current study). Folsom groups have been assumed long-distance travelers due to the occurrence of Folsom projectile points across a large area. Frison (1991) illustrates a number of Late Prehistoric side- and corner-notched projectile points on the northwest Plains while I myself have found near identical arrowheads in Oklahoma, yet we do not assume long-distance travel for Late Prehistoric Plains groups. Rather, we categorize these Late Prehistoric groups into *phases* and *foci* based on a number of spatial, environmental, architectural, artifacts, and resource-use factors. We use the small differences between these categories to draw specific conclusions about even more specific groups of people. Similar categories of Folsom-age people can be formed when comparing landscape and resource use as a starting point to understand who these groups of people were and how they interacted with each other; a very uncommon concept in the study of Folsom and other Paleoindian-age people, but very common study among almost any other human group in North America.
