Oklahoma State University

Small Grain and Ryegrass Forage Variety Tests in Oklahoma

W. E. McMurphy
Department of Agronomy

The small grains (wheat, rye, oats, and barley) are the highest quality forages which can be produced over all of Oklahoma. Steer gains from small grain pasture have consistently been superior when compared to other Oklahoma forages.

Steers on wheat pasture gained 1.7 pounds/day, then subsequent feedlot performance of these was equal to that of steers which gained only 0.9 pounds/day on bermudagrass hay (Horn, et al. 1974). Thus, its value for preconditioning steers prior to going into the feedlot was apparent. However, the forage appears to be inadequate in available calcium and magnesium, and may be higher in phosphorus than necessary for the diet of cattle. Mineral supplementation should be based on these needs. The *in vitro* dry matter digestibility ranged from 76 to 48 percent, but it has a very fast rate of digestion compared to bermudagrass hay. This rapid rate of digestion plus very high crude protein and non protein nitrogen content may be responsible for amino acid imbalances in the animal as well as potentially toxic levels of ammonia production in the rumen.

In two years of testing at Muskogee where wheat and rye forage was harvested four times a year, approximately 6-8 pounds of forage were sufficient for one pound of beef gain (McMurphy and Tucker, 1971 and 1972). Forage was harvested four times during the season about like most variety tests. However, with less frequent clipping, an unrealistic greater forage production

Research reported herein was conducted under Oklahoma Station Project No. 1474.

The author wishes to acknowledge the following persons for their cooperation with the research reported in this publication: James Arnold, David Boyer, C. E. Denman, Rhea Foraker, Dan Hane, Raymond Peck, Larry Phillips, H. Eugene Reeves, and William Senter.

Reports of Oklahoma Agricultural Experiment Station serve people of all ages, socioeconomic levels, race, color, sex, religion and national origin.

occurs. The conditions for these studies were ideal, and 400-pound steers gaining 2 pounds/day should consume 11 pounds of forage (oven dry) daily (National Academy of Sciences, 1970).

One problem faced by producers is the production of an adequate quantity of forage. Previous variety test results were reported by Denman and Arnold (1970).

The purpose of this publication is to summarize several years of small grain variety testing and some cultural methods to facilitate greater quantity of forage production.

Methods

All forage data reported herein are oven dry weights from four replications in each study. The standard dryland plot size measured 5 feet by 20 feet with rows 12 inches apart. The yield sample was mowed from the three center rows. Seeding rates were approximately 100-120 pounds/acre for the small grains. Precipitation at each location for the growing season is presented in Tables 31-35.

Test locations are shown in Figure 1 and the only irrigated test was at Goodwell. Information on soil test, soil series, seeding date, and fertilizer applied are presented with each table of the results. The experimental design was randomized complete block.

Results

There are many good varieties available, but no one variety has been consistently superior at all locations. Since fall and winter forage supplies are often limiting, it is important to select varieties capable of providing early production. Rye is noted for this characteristic, but if seeded early enough, many wheat varieties can compare favorably with rye for early growth. If adequate spring moisture is available, wheat will provide about 2 weeks longer grazing than rye. If moisture is still abundant at the time, ryegrass will continue to produce after wheat has ceased growth. A word of caution is necessary about ryegrass because its growth habit and weedy nature would be quite comparable to introducing cheat into a wheat field used for grain production.

There are too many varieties available to test continually, thus many good varieties are no longer included in current tests. A method described by Patterson (1950) to adjust for the year effects was used to compute a comparative summary of forage production at each location. Bonel rye has been tested every year at every location and serves as the standard for our comparisons. This comparative value is based on the yield of each variety expressed as

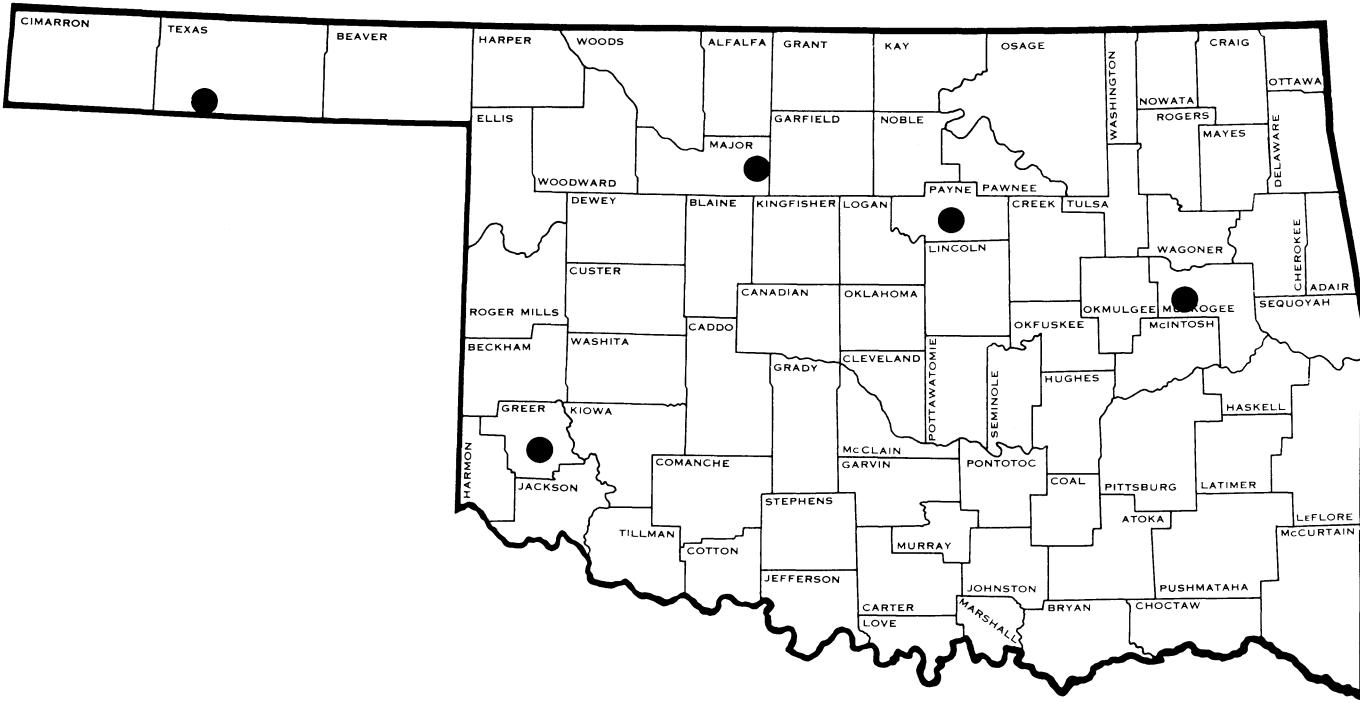

Figure 1. Locations of Small Grain and Ryegrass Forage Variety Tests in Oklahoma.

percent of the yield of Bonel rye only in the years the variety was tested. Included in this comparative summary are data from Denman and Arnold (1970). Performance of those varieties tested more than one year is more reliable; therefore, they are listed first in the comparative summary tables.

Goodwell

Irrigated small grain varieties have been seeded in August each year. With this early seeding date rye has shown no advantage over wheat for fall and winter production (Tables 1-6). Since wheat is usually more productive than rye in the spring, the wheat varieties have often outproduced rye in total forage (Table 1). Several varieties seem to excel here, but not at other locations. Kerr barley, DeKalb 9190 and some triticale varieties compare rather favorably to rye production.

Lahoma

The rye varieties have been consistently high producers with Bonel being superior (Table 7). Among the wheat varieties, DeKalb 582, Sturdy, Triumph 64, Centurk, and Osage were good producers. Linn perennial ryegrass produced good late spring forage in only two of the four years that it was tested (Tables 8-12).

Mangum

If the objective here is to produce fall and winter forage, then there is only one species choice, rye. Fortunately, there are several good varieties of rye to select from (Table 13). Limited moisture is often a critical factor which prevents early seeding; however, the value of early seeding if possible is reflected in the 1971-72 and 1973-74 season data (Tables 15, 16).

Muskogee

The total environment at Muskogee is different from the rest of Oklahoma. The growing season precipitation is greater. The Taloka and Parsons soils have a clay pan which restricts downward water movement in the profile. This plus excessive precipitation results in water logged soils over considerable periods of time and may well be responsible for the relatively lower forage production obtained at Muskogee in comparison with other locations in Oklahoma.

The ryegrasses have proven remarkably well adapted to these wet soils and have produced significantly greater total forage than any of the small grains (Table 19). However, much of this extra forage is produced later in the spring than the small grain (Tables 21-24). Furthermore, to secure fall pro-

duction, a late August seeding date is necessary. Then the forage should be fully utilized by late December. Ryegrass has been topkilled by severe cold and only dead, brown, vegetation was available for winter grazing resulting in poor steer gains until new spring growth commenced. Possibly in southeastern and south central Oklahoma the temperature may not be severe enough to kill the topgrowth. Average daily gain of steers on ryegrass was about 73 percent that of steers on small grain pasture (McMurphy and Tucker, 1974).

The difference between Bonel and Elbon rye is much less here than at other locations. Some of the noteworthy small grain forage varieties are Bonel rye, Elbon rye, Scout 66 wheat, DeKalb 582 wheat, Osage wheat, Centurk wheat, and Triumph 64 wheat.

Perkins

Outstanding varieties at Perkins have been Bonel rye, Maton rye, Scout 66 wheat, and Centurk wheat (Table 25). Moisture conditions during these seasons have been excellent at this location.

Summary

The five locations where these tests were conducted in Oklahoma are from widely different soils and climates. Generally, the ryegrasses excel at Muskogee where wet soils prevail, but ryegrasses are very poor producers at Mangum. On the dry sandy soils at Mangum, rye varieties are superior. Then with the early seeding and irrigation at Goodwell, the wheat varieties excel.

These data are provided to assist producers in various areas of Oklahoma to select those varieties best suited to their needs.

OKLAHOMA

Agricultural Experiment Station

System Covers the State

Main Station — Stillwater, Perkins and Lake Carl Blackwell

1. Panhandle Research Station — Goodwell
2. Southern Great Plains Field Station — Woodward
3. Sandyland Research Station — Mangum
4. Irrigation Research Station — Altus
5. Southwest Agronomy Research Station — Tipton
6. Caddo Research Station — Ft. Cobb
7. North Central Research Station — Lahoma
8. Southwestern Livestock and Forage Research Station — El Reno
9. South Central Research Station — Chickasha
10. Agronomy Research Station — Stratford
11. Pecan Research Station — Sparks
12. Veterinary Research Station — Pawhuska
13. Vegetable Research Station — Bixby
14. Eastern Pasture Research Station — Muskogee
15. Kiamichi Field Station — Idabel
16. Sarkeys Research and Demonstration Project—Lamar
