MATHEMATICAL ABILITIES INVOLVED IN CERTAIN NINTH GRADE GENERAL SCIRNCE TEXTBOOKS

By

SULVIA GLEMZEQ RGOUEBINS<br>Bachelor of Beience<br>Contral State Teachers College<br>Bomond, OkJahona<br>1931

Submitted to the School of Education Oklahoma Agricultural and Nechanien College

In Partial Pulfillment of the Requirements
For the Degree of MASTRR OF SCIENCD

1939

## APPROVED:

119454

## PHBEACE

The purpose of this survey was to determine the ratheratical abilities involved in certain ninth grade sonoral seience textbooks. An anslysis of these textbooks was made and the different mathematical concepts and mothenatioal abilities were counted, averaged, and tabulated. It is hoped that this inforfation wheh has been conpiled will be of assistance to interosted teachers.

The writer wishes to express her apprecietion to the following people for their guldance and assistance:

Guy a Lackey, associato Propossor of Bducation, rity bind and ancouraging edviser.

Chatles b. Rezer, Frofessor of Seconcary pacation.

Dr. James E. Zant, Associate Protessor of mathematics.

Clarence M. Pruitt, Associate Professor of gaucation.

## CHAPTER I

## INTRODUCTION

Junior high school science today is almost universally centered around environmental problems. Before studying general science, it would be well if the students could be acquainted with the different mathematical concepts and the different mathematical processes and principles required in handling the formulas and problems in ninth grade general science. It is charged that the opportunities for a closer correlation and integration of mathematics with "more vital" subjects, such as the social studies and general science, are almost completely ignored.

Dissatisfaction has been expressed by some teachers of general science in regard to the lack of mathematical ability on the part of the students to cope with the mathematical situations required in general science. Since mathematics is a tool for all sciences, it is well that some heed should be given to these. 1
According to Morton:
There are many situations of life in which order, magnitude, and quality are essential elements. Arithmetic is a systematic pattern of thinking about such situations. It is also a series of modes of attack upon them. It is thus more than a tool which one may use in the interpretation of personal, business, social, or civic affairs. It grows out of a productive study of such affairs and is applicable to them.
R. L. Morton, "The National Council Committee on Arithmetic," The Mathematics Teacher, Oct., 1938: Vol. XXXI, \#6, p. 267.

There is no doubt that much of the difficulty confronted by ninth grade general science students is due to their inability to interpret the situations which are expressed, due to a lack of previous training in some other field, such as mathematics or general reading ability. For this reason, science is having difficulty in establishing itself in the present program of studies. Judd ${ }^{2}$ states that some phases of science, such as psychology, geography, and physiology, have been discontinued ahd have been replaced by new subjects, such as agriculture, home economics, and general science which have a great deal of practical material in them. He attributes these fluctuations to psychological causes. He also contends that there is a natural interest on the part of everyone to be attracted by science, but that due to the teaching of science by specialists in other fields who have emphasized their fields at the expense of science, interest in science has suffered. If the school is to help pupils master science, it must arrange the science work in conformity with their abilities.

There is no doubt that science is dependent to quite an extent upon mathematics for its success. Likewise, it is true that the study of nature was one of the factors

Charles H. Judd, Psychology of Secondary Education, p. 325.
that promoted the devolopment of muthenctics. This close relationship is very ably expressed by Young when he expresses the idea that although mathonatics as a type of thought seems to inhere in the human mind, it was the study of nature that prompted and stimulated methematioal thought in the begiming because the phenonens of nature could not be understood without mathemetics.

According to Judd ${ }^{4}$ : selence developes only when probleas are understood. "In short it is the unfamiliar wich presents obvious problems. ${ }^{5}$

It hes been said ${ }^{6}$ that wathematies throws Iight on meny guestions that have trounled philosophexs for centuries. The cuestions of time, space, motion, and trath consronted in science are puzzline, and it is only through the concepts of metrematies thet we have ween able to comprehend then.

In order to detemine just what netionatical ooncepts and abilitiss are essential for the suecessfui handing of the various scientific suojects several surveys and studies have been made.

Williams made a detailed analysis of the mathematical abilities assential for freshman chemistry as revealed by a survey of a chemistry textbook written by W. A. Noyes. All mathematical concepts were listed and frequencies noted. All problems were solved and the principles involved with frequencies were tabulated. He found that practically all of the concepts and mathematical principles were those that occur in arithmetic. 8
Congdon made a survey to attempt to determine the mathematics essential for success in first-year college physics and first-year college chemistry. He used textbooks for this survey. His research revealed that in both subjects the algebraic equations involved were not difficult, and that there were few geometric facts involved.

Rendahl ${ }^{9}$ made a detailed analysis of three high school chemistry textbooks and found that multiplication occurred more frequently than any of the other processes. The algebra was of the simplest form and the geometry was negligible.
L. W. Williams, "The Mathematics Needed in Freshman Chemistry," School Science and Mathematics, Vol. XXI, October, 1921, pp. 654.65.

8
Allan Ray Congdon, The Training in High School Mathematics Essential for Success in Certain College Subjects.
J. L. Rendahl, "The Mathematics Needed in Solving Problems in High School Chemistry," School Science and Mathematics, Vol. XXX, June, 1930.

Lamb ${ }^{10}$ in his survey of ten hygiene books used in Grade 5 , found that very little arithmetical knowledge was necessary.

Shoptaugh ${ }^{11}$ made a survey of the adopted textbooks used in the state of Louisiana for high school in physics, chemistry, biology, and general science. He found that the mathematical concepts essential for chemistry, biology, and general science were rather numerous and pertained to denominate numbers. The mathematical abilities for biology and general science were negligible while those for chemistry were chielly arithmetical. The mathematical concepts essential for physics were rather numerout pertaining largely to geometry, algebra, and denominate numbers. The mathematical principles in physics were chiefly algebraic.

In order to ascertain the amount of mathematies involved in general science according to present texts used, five modern general science books have been surveyed to determine just which mathemetical principles and concepts appear in order that interested teachers may have some sort of a guide to assist them in determining just what

Theldon N. Lamb, The Amount of Arithmetic Necessary for a Child to Know in Order to Read Intelligently a Fifth Grade Hygiene Book, Thesis, 1931, Ann Arbor, Michigan.

11
John Royal Shoptaugh, The Mathematics Needed for Science Courses in the Louisiana High Schools, Thesis 1931, Louisiana State University, Louisiana.
mathematics is found in the text. "At all levels the courses in mathematics should include such mathematical information as is of greatest immediate value to the pupils." ${ }^{12}$ If a teacher has the above principles and concepts in mind, it will be much easier to detect them and stress them in the mathemstical courses. Then, too, as stated by the National Conmittee of Mathematical ${ }^{13}$ requirements:

The primary purpose of the teaching of mathematics should be to develop those powers of understanding and analyzing the interdependencies of quantities and spacial magnitudes which are necessary to a better appreciation of the progress of civilization and a better understanding of life and of the universe about us, and to develop those habits of thinking which will make these powers effective in the life of the individual.
B. R. Breslich, The Administration of Mathematics in Secondary Schools, p. 185.

## CHASTER II

COLECMIO ADD RREATMET OR DATA
The purpose of this survey is to determine the inportance given to the dirferent mathenatical abilities in ninth grade general science as judged by the frequencies of their appearence in the textbooks surveyed. It is not the purpose of this survey to compare the textbooks in any manner, but rather to obtain an average or the different abilities required as is shown by the frequencios of their appearance. A list of the textbooks surveged and the aboreviation that is used for each in the tables aay be found in the appendix.

In the formation of the tables, methoas used and mords complied by Congdon ${ }^{1}$, Willians, ${ }^{2}$ oscumn, ${ }^{3}$ Lamb, $4^{4}$ and shoptaugh have been considered. The five toxta have been read and a word count taren. The coneapts have been classed and recorded in tadles in groups of aenoninate numbers of the Bngish Systom and Standard Moesurementa, denominate nuabers of the metrie dysten, other terms of reasurcment, geonoticic terms, and some miscelleneous mathomotical concopts. All numbers have been counted

```

and tabulated as to whether they were writton in figures, words, or combinations of figures and words. The numbers have also besn tabulated acoording to their denoninational size. All syabols appearing in the exposition have been counted and tabulated. The graphs, formulas, meps and oharts that involve cuantity eppearing in the texts have been counted and tabulated. All laboratory experiments have been considered, and the mathematical abilities required, such as measuring ond araving have beon tabulatea. All problems heve been solved and the general principlos, specific processes, und fundamental processes used have beor wobulated.

Two spocial symbols heve boen used in the tablea. She syobol, (f), after a word signifios that the concept has appearea ten thes or more in the exposition of the text. It is considered that if a term appears at least ten times in a test, it is worthy of being accreuited high importance. The sign, (f), after a number or process signifies that a aesinite count was iapoasible, due to the fact that more than one solution was possible for the problem. This was especially true in the dietary probleas.
I. Watrematical Concepts.
A. Doncepts of Heasuranent.--Tables I, II, and

III list the different concepte of measuremont used in the five texts. These concopts are classified under
"Denominate Numbers of Snglish System and Standard Measurements" in Table I, "Denominate Numbers of Metric System" in Table II, and "Terms of Heasurement" in Table III.

From a word count of the exposition in the five texts, the frequencies were noted, an average was computed, and the results of both findings were tabulated. As has been previously stated, any concept appearing ten times or more has been marked with a (i). All forms of the word have been listed undar one headinc.

Tables I and II reveal the pact that concepts of measurement have been usod quite extengively. Listing the abbreviations and symbols for one quantity, (Ex. peet, ft., '), as one, Table I shows that there are forty different concepts of the Anelish Bystem and Standird Neasurements need. Claseifying the terms as to area, length, mass, time, and volune, Table $I$ shows that there were ten differont tares pertaining to length, nine to volume, eight to time, five to mass, four to area, and four to quantity. The above shows that out of the forty concepts listed in Toble I, length ranked first vith 25 per cent of the total terms.

Pourteen different concepts of the Metric System appeared in Table II. Out of this total of fourteen, seven expressed lenget, five mess, and two volume.

Length, also, ranked first in this table with 50 per cent of the total. Since both of the denominate number systems have been studied before the student reaches the ninth grade, the use of them should not cause too much difficulty.

Table III lists miscellaneous units of measurement that pertain to various scientific principles. Some of them, as the watt, are somewhat familiar to the students because of the comion use of electricity in most homes. However, the scientific terms of measurement used in the texts are clearly defined. The uses of these scientific terms in problems are also explained and illustrated. Table III, also, has some concepts listed that are not quite so scientific. Such terms as arm's length, drop, dose, etc. are illustrations of these. They have been included in the table because they are practical, are used quite extensively, and should be apprehended.
B. Geometric Concepts.--Table IV contains a list and the frequencies of the geometric concepts used. There are 47 terms in all which is quite a broad range. At the time the students take ninth grade general science, they have not yet had geometry as a specisl study. However, a survey of Table IV shows that all geometric concepts used are those which appear in the elementary geometric work included in the intuitive and demonstrative geometric units offered in the seventh and eighth grades.
C. Wiscellaneous Mathematical Concepts-Table V
includes a list of ciscellaneous methematical concepts that are not included in any of the provious classifications. They are definitely matheratical, however, and should be given recognition. The aoasuring devices listed are included because they are used to determine quantities. There are one hundred and thirteen of these concepts. With the exception of the different measuring devices and the inverse proportion torm, the words are cuite comon to seventh and eightr grade work. The measuring devices are explained in each of the texts in wich tiey appear. The term inverse proportion is merely mentioned in regard to the density of light. Wowever, the process of comparing the densities of light at different distances is explained quite simply. The table shows that the expression appears on an average of .4 times so is, thererore, quite negligible.

D. Number Concepts.--Tables VI, VII, VIII, and IX deal with the number concepts. The number concepts are classified as numbers in figures, numbers in words, numbers in combinations of figures and words, and numbers rated according to size. Comparing Tables VI, VII, and VIII, it will be found that out of the 19,350 number concepts appearing in all five texts, 57 per cent of them are written in figures, 42.8 per cent of them are written in words, and .1 per cent in combinations of figures and words.

1. Numbers in Figures.--Table VI has a list of all the numbers that appear in figures in the texts. In compiling this list, the numbers of the pages, exercises, tables, diagrams, etc. were not counted. The numbers in this group covered a very broad range. They ranged from quantities expressed in fractions to quantities expressed in 21 digits. The table shows that 76.7 per cent of the numbers used were whole numbers. This table, also, shows that students in the ninth grade should be able to read and comprehend to a certain extent large numbers.
2. Numbers in Words.--Table VII contains a list of all the numbers that appear in words. Out of the average of 1656.6 words to each text, 76.3 per cent of these are whole numbers. The numbers appearing in words range from fractions to ten trillion.

## 3. Numbers in Combinations of Figures and

 Words.--Table VIII has all the numerical concepts that appear in combinations of figures and words. In this group, as in the two groups previously listed, the majority of the terms are whole numbers, 93.7 per cent of them being devoted to this group. These numbers range from "I thousand" to "66 with 33 ciphers."4. Numbers Rated According to Size.--Table IX has all the numbers listed that appear in Tables VI, VII, and VIII arranged according to size. It may be readily seen that the great majority of the terms used are of reasonable size containing only four digits or less. In fact, 89.65 per cent of them range in values from 0 to 1000. As can be noted from the table, the use of extremely large numbers is negligible. In the exposition of the texts, their use has been restricted almost entirely to expressing distances of the heavenly bodies.

E. Symbols.--Table X lists the different mathematical symbols that appear in the texts surveyed. The survey would be incomplete if the symbols were not included. The field of mathematics depends a great deal upon its signs and symbols to express its various processes.

The chemical sign, $(\longrightarrow)$, which signifies that the action is not reversible was used but once, and then, no computations were required with it; thus making its use negligible.
F. Formulas, Tables, Graphs, Maps, and Charts.-Table XI deals with the formulas, tables, graphs, maps, and charts found in the five texts. In selecting these, only those pertaining to quantity in some manner were chosen.

As the table shows, two of the texts did not include the formula for "Horse Power". Even though they did not actually have the formula written out, they made use of it. That is, they either had the rule written out in italics or they explained the process step by step. Table XIII, "General Principles Involved", shows that many of these formulas were actually used in each of the texts even though they didn't appear as a formula in the exposition. There was on an average of 12.8 chemical formulas for each text, but they were merely mentioned in the exposition and required no mathematical
computations. Table XIII, also, shows that other formulas common to arithmetic are required.

The tables, graphs, maps, and charts listed were restricted solely to those comparing or expressing quantitative values. Table XI reveals the fact that tables, maps, charts, and graphs were used quite extensively, there being on an average of 50.2 of them to each text. This is well, because there is no more striking way of expressing statistical facts than by one of these devices.

II. Mathematical Computations

Two ways of making mathematical computations
OCT 27
1939
are by laboratory work and by problem solving. Tables XII, XIII, XIV, and XV deal with mathematical computations. In compiling these tables, it was necessary to adopt a sign for indefiniteness. The sign, $(f)$, placed after some of the reports signifies that it was impossible to get an exact count due to the indefiniteness of the assignment. In each of the se cases, a reasonable minimum was recorded.
A. Laboratory Work.--Table XII tabulates the different physical requirements asked of the students under experimental work. The terms are expressed quite definitely and should be easily interpreted. The expressions, such as, "Cube of definite dimensions, Comprehend", have reference to the fact that the students were asked to use a cube of definite dimensions for an experiment. Therefore, it was considered a laboratory skill that should not be omitted.
B. Problem Solving.--Tables XIII, XIV, and XV are concerned with problem solving. All problems occurring in the laboratory work, exercises, assigned problems, and explanatory problems were solved and the different principles, processes, and fundamentals involved for each problem were recorded. The explanatory problems were included because it seemed justifiable that the students
should understand and be able to solve not only the problems asked of them but also those explained in the texts.

1. General Principles Involved.--Table XIII records the general principles involved in solving the problems. These principles have been classified under eleven headings, namely: Average, Buoyancy, Dietary, Electricity, Energy, Longitude and Time, Machine, Mensuration, Percentage, Specific Gravity, and Thermometer Problems. The table shows that 25 per cent of the computations required were concerned with machine problems, 17.1 per cent with energy problems, and 11.8 per cent with dietary and mensuration problems each. The majority of the principles used were concerned with machine and energy problems. The students have not had these in the seventh and eighth grades. However, since these are problems that are based definitely upon formulas and the formulas are given in the texts, the students should be able to solve them as they have had substitution in formulas in the seventh and eighth grades.
2. Specific Operations Involved in the Problems.-TTable XIV includes the specific operations involved in the solving of the problems. As will be noted from the table, these are processes that occur within the problems mentioned under general principles in Table XIII or processes that are concerned with simple problems that do not have one of the principles mentioned in Table XIII
involved. It may be noted from Table XIV, that a formula was used on an average of 39.4 times to each text.
3. Fundamental Processes.--Table XV lists the four fundamental processes with their frequencies, average to each text, and per cent of each kind involved. These processes were compiled by keeping an actual count of each time they occurred in the computational work. As may be noted, none of these were definite. However, in arranging these, a plan was devised to make them consistent. The dietary problems were especially very indefinite. In recording the processes for these, in order to be consistent for all, each dietary problem was assigned one addition, ten multiplications, one subtraction, and five divisions. The table shows that 51.7 per cent of the mathematical computations required in the fundamental processes were devoted to multiplication.

## LABORATORY WORK

## CHAPTER III

## SUMMARY AND CONCLUSIONS

This survey of the mathematical abilities involved in certain ninth grade general science textbooks has revealed the following facts:

1. Denominate numbers have been used quite extensively throughout the five texts. Forty different concepts of the English System and Standard Measurements were used with an average of frequencies of $302.6 f$ to each text. Of the Metric system, 14 different concepts appeared with an average of $37 f$ to each text. Besides the 54 different concepts just mentioned, 36 other concepts of measurement were used, making a total of 90 concepts of measurement used. The majority of the concepts expressed in the English and Standard Measurements, and Metric systems were devoted to length, with volume, mass, and time following in their respective orders. Terms applying to area and quantity appeared least with four different terms of each.
2. Geometric concepts were used frequentiy. Fortyseven different geometric terms appeared in the five texts. These terms, however, are terms that are used in the intuitive and demonstrative geometrical work of fered in the seventh and eighth grades. Besides the geometric concepts, 113 miscellaneous mathematical concepts were found.
3. The survey showed that there were many number concepts. Out of the total of 19,350 number concepts, 11,035 of these appeared in figures, 8,283 in words, and 32 in combinations of figures and words. Or, quoting in per cent, 57 per cent of the numerical concepts were expressed in figures, 42.8 per cent of them in words, and . 4 per cent of them in combinations of figures and words. The range of the number concepts was very broad, ranging from zero to numbers with 35 digits. However, 89.65 per cent of them ranged in values from 0 to 1000.
4. With the exception of one chemical symbol, all the symbols used were simple arithmetical signs. There was no work assigned for the use of the chemical sign, therefore, its appearance was negligible. Seventeen different arithmetical symbols appeared in the five texts.
5. Noting the tables, graphs, maps, charts, and formulas comparing or expressing quantitative values that appeared in the five texts, it was found that there were 251 in all with an average of 50.2 to each text. Out of the 73 graphs listed 39.7 per cent of them were picture graphs, 27.3 per cent were bar graphs, $26+$ per cent were circle graphs, and 6.8 per cent were line graphs.
6. Laboratory work has been used frequently throughout the texts. Out of the $2110 \neq$ laboratory skills required of the students, 1202 , or an average of 240.4 to each text, of these were devoted to measuring by the use of denominational numbers.
7. In the problem solving, there were on an average of 55.6 general principles used in each text. Out of the 11 different general principles involved, 25 per cent of them were concerned with machine problems, 17.1 with energy problems, 11.8 per cent with dietary problens, and 11.8 per cent with mensuration problems.
8. In the specific operations involved in problem solving as listed in Table XIV, there were on an average of 60.6 to each text. Out of this number, the formula was used on an average of 39.4 times in each text, thus indicating that the formula is quite an important factor in solving scientific problems. This is not only true in science but in practically all fields that use mathematics.

## Ligda said:

Every situation in a problem is governed by a characteristic formula. The recognition of such situations and of their characteristic formulas is essential to the understanding and solution of the problem.
9. There were on an average of $303.2 f$ of the four fundamental operations included in each text. Of this number, $51.7 f$ per cent of them were concerned with multiplication, 23.6 per cent with division, $19.1 f$ per cent with subtraction and $5.4 \nmid$ per cent with addition.

Paul Ligda, The Teaching of Elementary Algobra, p. 117.
