A thirty-year-old lady presented with chronic, postprandial abdominal pain associated with decreased appetite and weight loss. She had a past medical history of ulcerative colitis and past surgical history of Nissen fundoplication, hysterectomy and bilateral oophorectomy for endometriosis. Enhanced computed tomography (CT) of the abdomen/pelvis displayed severe narrowing of the celiac artery (CA) at the level of its ostium (Panel A) with post-stenotic dilatation. In an abdominal vascular ultrasound with respiratory maneuvers we saw a peak systolic velocity (PSV) in the CA during inspiration of 295 cm/s. The PSV was 108 cm/s during expiration for the CA. Peak systolic velocity in the superior mesenteric artery (SMA) was 424 cm/s during inspiration. Magnetic resonance angiogram (MRA, Panel B) showed compression of the SMA with post-stenotic dilatation. No signs of perivascular inflammation or fat stranding were appreciated. Serology studies workup showed only weakly positive anti nuclear antibody (ANA) titer. A mesenteric angiography (Panels C and D) illustrated progression to occlusion of the CA, a dynamic compression of the SMA with kinking mainly during expiration, and post-stenotic dilatation. The pre-operative suspicion for dynamic mesenteric vascular compression syndromes was intra-operatively confirmed with associated scarring along the CA and SMA via the arcuate ligament.

Panel A.
Enhanced computed tomography showing severe narrowing of the celiac artery.

Panel B.
Compression of the superior mesenteric artery on magnetic resonance angiogram (MRA).

Chronic mesenteric ischemia is usually due to atherosclerosis, although it can rarely be caused by fibromuscular dysplasia, segmental arterial mediolysis, or trauma.¹ Median arcuate ligament syndrome (MALS) is the dynamic compression of the CA by the median arcuate ligament of the diaphragm, typically seen in middle-aged females complaining of postprandial abdominal pain, emesis, and weight loss. The diagnosis is classically made

Panel C.

Angiogram with progression to occlusion in the celiac artery.

Panel D.

Kinking and post-stenotic dilatation of the superior mesenteric artery on angiogram.

by angiography, with less invasive diagnostic measures such as Duplex arterial ultrasonography emerging as an important testing modality. As our case confirmed, rarely the CA and SMA can be externally compressed simultaneously in the same patient.²

The treatment is surgical division of the median arcuate ligament.³ This is curative, although surgical bypass is sometimes necessary. Dynamic vascular compression syndromes are unusual entities. They should be strongly considered as part of the differential diagnosis of chronic mesenteric ischemia without atherosclerosis.

Declaration of conflicting interest

The authors declare that there is no conflict of interest.
