

Polymers, Inc.  
Calvert City, Kentucky  
Project Manager

To Whom It May Concern:

Our team has submitted our optimized design and financial projections for a grassroots nylon 6,6 manufacturing facility in Calvert City, Kentucky.

We have submitted a spiral-bound document containing the main body of our report, our process flow diagrams with control scheme, our equipment and financial tables, and an appendix containing any other relevant material to this project.

Per your request, economic analysis has been performed over the standard ten-year project life in order to identify the most profitable nylon 6,6 manufacturing process. We have closely examined different methods of nylon 6,6 production and have concluded that a melt-phase polymerization process resulting in nylon pellets is the most attractive choice from an economic, safety, and feasibility standpoint. This process has been optimized, a control strategy has been created, and health, safety, and the environment has been extensively considered.

We conclude that this process will require a capital investment of \$2.26 million. Full-capacity annual operating costs will be \$2.34 million. The payback period is 0.337 years and the discounted cash flow rate of return over a ten-year project life assuming a 15% internal rate of return is 333%.

If you have any other questions, please feel free to contact us.

Sincerely,

Process Engineering Team

**MANUFACTURING FACILITY FOR NYLON 6,6**

**AIChE Student Design Competition**

March 9, 2017

## EXECUTIVE SUMMARY

---

The nylon 6,6 polymerization process contained herein was made in accordance with the problem statement and standards put forth in the 2017 AIChE Student Design Competition. This design was created using Aspen Plus software, which was rigorously compared to an empirical model created in Microsoft Excel to ensure its validity. Various process design elements were considered, but the ultimate design was selected due to its merits from safety, economic, and practicality standpoints. The proposed design for converting aqueous adipic acid (ADA) and hexamethylenediamine (HMDA) utilizes two reaction stages in order to achieve 90% conversion of the feed materials. In order to promote high conversion of feed and keep the nylon in the melt phase, high temperatures and pressures are necessary. Regular maintenance and inspection will help to ensure that no equipment is damaged. These risks and others such as startup and shutdown, chemical hazards, loss of containment, emissions to air, and waste management have been carefully identified and mitigated through a series of active and passive safety measures.

Although spun nylon fiber has a higher sale price, it adds considerable complexity to the process and thus is inherently less safe. Instead, the nylon product is shaped into pellets using a pelletizer. This product will be sold for an estimated \$1.18/lb based upon nylon market projections. In the future, it would be easy to add the equipment to turn the nylon pellets into fiber if further analysis deems it beneficial.

It was requested to design the process so that the process output could be turned down to 67% of its full capacity should demand for nylon 6,6 decrease. The process control scheme aids in this feat; by changing the temperature in the second reaction stage, the process will output the same quality nylon product at a 67% capacity.

The capital cost necessary to construct this grassroots process facility in Calvert City, Kentucky is estimated to be \$2.26 million. A total of 29 operators will be needed for an annual cost of \$1.89 million. If it is assumed that the plan is running at full capacity for a year, the annual utility costs are estimated to be around \$450,000. However, the payback period is only 0.337 years as the project annual revenue is \$106 million annually. Even if the case was run at 67% of the capacity, the process would still be immensely profitable. See the table below for more details.

	<b>Capital costs</b>	<b>Utility costs</b>	<b>Labor costs</b>	<b>Revenue</b>
Full Capacity case	\$(2,260,000)	\$(450,000)	\$(1,890,000)	\$106,000,000
Turndown case	\$(2,260,000)	\$(310,000)	\$(1,890,000)	\$70,000,000

Based upon these estimates and assuming a 10-year project life with a 40% tax rate, economic analysis was performed.

	<b>NPV</b>	<b>DCFROR</b>	<b>PWC</b>	<b>Payback Period</b>
Full Capacity case	\$34,300,000	333%	\$(2,370,000)	0.337 years
Turndown case	\$20,300,000	212%	\$(2,370,000)	0.514 years

Based upon these economic analyses, it has been concluded that this process is very desirable. It is recommended to move into the detailed design stage.

## INTRODUCTION

---

For this project, the design team is tasked with the preliminary design, optimization, and economic analysis of a nylon 6,6 production process from adipic acid (ADA) and hexamethylenediamine (HMDA) feed. This grassroots facility is to be located in the Calvert City, Kentucky area. In order to meet the growing nylon demand in the United States, this process must produce 85 million pounds of nylon 6,6 per year. In the instance that demand slows for any period of time, this process must also be able to be turned down to 67% of its full capacity. Safety and sustainability are of the utmost importance in the design of this production facility. Safety measures and a control strategy must be designed and discussed. The team is able to select the type of nylon production process (aqueous or melt phase polymerization) as well as the form in which the nylon (fiber or pellets) is sold. In-depth scientific research, computer-based process modeling, safety considerations, and economic analysis have been used to make each decision about the process. A discussion of each of these design considerations can be found in the body of this report.

Nylon 6,6 (also called nylon 66, polyamide 66, and PA 66) is a very versatile and widely-used polymer as it can be made to behave as both a plastic and a synthetic fiber. It was first created in 1934 in the laboratory of Wallace Hume Carothers, the father of synthetic polymer science. Donald Coffman, a member of Carothers' team pulled a sample of the fiber from an adipic acid and HMDA combination experiment. It was noted that this fiber was strong, elastic, and insoluble with a high melt temperature. This fiber came to be known as polyamide 66 because each carbon-containing unit was composed of six carbons. DuPont decided to manufacture these fibers under the name "Nuron", but was soon renamed to "Nylon" as it is known today. When it first hit the market, nylon was used for women's hosiery because of its high stretch and silk-like feel and appearance. By late 1941, nylon was used almost exclusively for military parachutes and harnesses during World War II.<sup>1</sup> Over the years, nylon 6,6 grew in popularity for clothing and home furnishings such as carpets and upholstery.<sup>2</sup> Most carpets are composed of nylon fiber because of its high abrasion resistance and ease of dyeing. Nylon fibers can also be found in toothbrush bristles and spandex-containing clothing like swimsuits and athletic shoes. Nylon 6,6 is often used in the rubber industry in the form of conveyer belts and tires due to its high melting point, dimensional stability, and moisture resistivity. Heavier aircraft and off-road vehicles contain nylon-reinforced tires, which results in safer air

<sup>2</sup> Nexant CHEMSYSTEMS. "Nylon 6 and Nylon 6,6 Report Abstract." Web.

landings and road travel.<sup>3</sup> Recently, however, a higher proportion of nylon has been manufactured as engineering thermoplastics due to its broad range of useful properties such as chemical resistance, high melting point, and toughness which make it particularly well-suited for the electronics and automotive industries. Nylon thermoplastics are advantageous to use over metal parts due to their functional mechanical properties. These thermoplastics are lighter and less expensive than metal parts which aids in meeting environmental regulations for automotive emissions.<sup>4</sup> Some examples of thermoplastic applications include drive shafts, bearings, nuts, bolts, and even wheels.<sup>5</sup> According to the American Plastics Council, the 2010 US production of nylon thermoplastics was 1 trillion pounds and the production of nylon fiber was 1.3 trillion pounds.<sup>6</sup>

**Figure 1:** Nylon 6,6 condensation polymerization reaction

Nylon 6,6 is a polyamide, meaning that it is a long, synthetic chain with recurring amide groups that can alter its structural orientation to produce a strong, versatile filament.<sup>7</sup> This polyamide is produced through a step-growth polymerization condensation reaction of aqueous adipic acid and HMDA. In the absence of a catalyst, the step-growth process initiates when one adipic acid molecule donates a proton to the carbonyl oxygen on another adipic acid molecule. This protonated oxygen is now ready to react with the nitrogen of the HMDA creating an ammonium intermediate. After another electron rearrangement, the amide dimer is formed while a water molecule is expelled and regeneration of the acid catalyst occurs. This is a reversible reaction, thus the expelled water molecules must be boiled off at high temperatures in order to increase conversion. Dimers can react

<sup>3</sup> Bagwala, Mufaddal. "Preparation, Properties and Application of Nylon 6,6 Fibers." Web. pg. 3-4, 9-10

<sup>5</sup> Bagwala. pg. 10

<sup>6</sup> Carraher, pg. 15

<sup>7</sup> Bagwala. pg. 1-2

with other dimers or diacids to form trimers, tetramers, and oligomers. Longer such chains continue to form as water is expelled until the desired degree of polymerization or molecular weight for nylon 6,6 is achieved. Running this process at high temperatures and low pressures or under a slight vacuum at later stages aids in water removal. The reaction is terminated when water is no longer removed.<sup>8</sup>

**Figure 2:** Block flow diagram for nylon 6,6 polymerization process

In order to create a continuous nylon 6,6 polymerization process, at least two reaction stages are necessary (see Figure 2). The aqueous adipic acid and HMDA feed must be mixed and reacted at high temperatures and pressures in either a continuous stirred tank reactor (CSTR) or plug flow reactor (PFR) in order to begin condensation polymerization. Water is formed as a byproduct of this reversible reaction and must be removed in order for the reaction to proceed. The pressure of the nylon solution needs to be lowered while keeping temperatures high in order to evaporate water from the solution. Pressure is reduced either through a series of throttling valves or the solution is flashed into a second reactor. This second reactor is a thin-film evaporator which is able to handle the high viscosity of the hot nylon and remove most of the water byproduct. After this second reactor, the nylon is at a high enough molecular weight to be used for thermoplastics or fiber. The nylon can either be extruded into sheets and cooled before crushing into chips or the molten nylon can be fed to a pelletizer which shapes the nylon before it is cooled and dried on a conveyor belt.

## DESIGN BASIS

---

This process is required to produce at least 85 million pounds of nylon 6,6 from adipic acid and HMDA annually. The process must be capable of a turn-down case of 67% of its full capacity. The ideal molecular weight of nylon 6,6 product is between 18,000 and 20,000 grams per mole as anything below 18,000 g/mol will lack the characteristic strength of nylon and anything above 20,000 g/mol is very difficult to spin into fiber and can get caught in process equipment.<sup>9</sup> This grassroots facility must be located in the Calvert City, Kentucky area. In order for this process to be considered a favorable investment, the process must be profitable with at least a 15% return on investment. A 10-year project life and a tax rate of 40% have been assumed.

**Table 1: Feed Component Prices (given)**

<b>Feed Component</b>	<b>Price</b>	<b>Units</b>
Adipic acid (ADA)	\$0.68	\$/lb
Hexamethylenediamine (HMDA)	\$1.13	\$/lb
Water	\$30.40	\$/million lb

Pricing trends from PCI Wood Mackenzie, an analytics company, have been utilized to predict future nylon 6,6 sales prices.<sup>10</sup> See Table 2 below for the anticipated sale price of nylon pellets and nylon fiber.

**Table 2: Nylon 6,6 Sale Price**

<b>Nylon 6,6 Form</b>	<b>Price</b>	<b>Units</b>
Pellets	\$1.18	\$/lb
Fiber	\$225	\$/100 meters

Since this is the preliminary design stage, the design scheme for all supporting utilities such as electricity, cooling water, steam, etc. is not required; however, these things must also be taken into consideration from an economic standpoint. Table 3 contains the anticipated utility prices which are used to estimate manufacturing costs.

**Table 3: Assumed Utility Prices**

Utility	Price	Units
Electricity	\$0.07	\$/kilowatt-hr
Fuel gas	\$3.80	\$/million Btu
Cooling water	\$120	\$/annual gpm

The limits of these utilities and other specifications for the process and the process location are given in Table 4.

**Table 4: Utility and Process Specifications**

Specification	Value	Units
Maximum ambient temperature	107	°F
Minimum ambient temperature	-9	°F
Absolute atmospheric pressure	14.13	psia
Cooling water supply temperature	87	°F
Cooling water return temperature	120	°F
Cooling water supply pressure	50	psig
Cooling water return pressure	35	psig
Cooling water fouling resistance	0.002	hr*°F*ft <sup>2</sup>
Instrument air pressure	85	psig
Elevation above sea level	341	ft

## TECHNICAL DISCUSSION

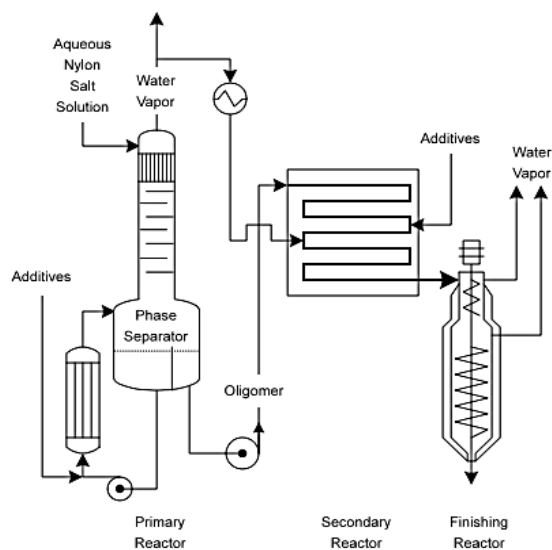

---

### Design Philosophy

There are two main industrial nylon 6,6 production processes - aqueous phase polymerization and melt phase polymerization. Both processes begin with the creation of a nylon salt which is composed of a 1:1 stoichiometric molar ratio of aqueous adipic acid and HMDA. The aqueous phase process may be completed in an autoclave (batch process) or in three reactor stages (continuous process). Historically, autoclaves with a 3-4 hour residence time were employed, but the industry has trended toward continuous processes for productivity, consistency, and safety reasons.<sup>11</sup> The newer, three-

<sup>11</sup> Billmeyer, Fred W. *Textbook of Polymer Science*. New York, Wiley, 1962. Print. pg. 431

stage process requires the consecutive use of a reactive distillation column, a loop-type reactor or series of throttling valves, and a wiped-wall evaporator. In the reactive distillation column, the aqueous nylon salt flows in the top of the column above the reactor. This drives off excess water. In the reactor vessel below the column, temperatures are between 230°C and 290°C and pressures are above 250 psig. A partial reboiler maintains good circulation throughout the reactor and removes water produced by the condensation reaction. The oligomers travel out the bottom of the first reactor and travel to a loop-style reactor or a series of throttling valves to reduce the pressure and remove more water. In the final stage, a wiped-wall evaporator is used to finish the reaction at temperatures of up to 300°C and at slight vacuum pressure.<sup>12</sup> See Figure 3 for the process flow diagram (PFD) for this process.

**Figure 3:** Process Flow Diagram for Aqueous Phase Nylon Polymerization

An alternative nylon 6,6 production process, melt-phase polymerization, has been developed more recently. The nylon salt solution is fed to a plug flow reactor (PFR) at temperatures near 275°C and pressures above 820 psig. At these high temperatures and pressures, the nylon salt is molten but does not boil. The residence time in this tubular reactor is usually between 15 and 30 minutes. The polymer solution is then throttled through a series of valves or a series of successively larger-diameter pipes. As the pressure is reduced, steam will be produced. Heating is necessary to keep the polymers from freezing and fouling the line. As in the aqueous phase polymerization, the final step involves the use of a wiped-wall evaporator which finishes the reaction around 300°C.<sup>13</sup>

<sup>12</sup> "Nylon 6,6 Step Growth Polymerization." *Aspen Polymers Handbook*, pg. 94–96

<sup>13</sup> *Aspen Polymers Handbook*, pg. 94–96.

Both the aqueous phase polymerization and melt phase polymerization processes result in the creation of nylon 6,6 ribbon, which travels on a conveyor belt as it cools. When it hardens, the ribbon is cut into chips, the finished product for plastics-grade nylon 6,6. Alternatively, the molten nylon may be fed into a pelletizer which turns the nylon into pellets before feeding them to a conveyor belt to cool and dry. In order to form nylon fiber, the chips or pellets are loaded into a hopper, melted via electric heater, forced through a spinneret (steel disk with small countersunk holes), and wound into fiber on large bobbins (see Figure 4). This spinning process can create, on average, 2500 feet of nylon fiber per minute.<sup>14</sup> The average ideal molecular weight for nylon fiber is between 18,000 and 20,000 grams/mole, but this molecular weight can be higher for thermoplastics depending upon the desired application.<sup>15</sup>

**Figure 4:** Melt Spinning Process to Make Nylon Fiber

Some of the main considerations for this project include choosing which of the two aforementioned nylon 6,6 production processes will be employed as well as whether the nylon will be sold as pellets or as a spun fiber. Both the aqueous phase polymerization and melt phase polymerization processes have been examined on a basis of design, economics, safety, and control. Based upon these analyses, the melt polymerization process has been chosen for several reasons: 1) it is more easily modeled as

<sup>14</sup> Billmeyer. pg. 431, 515

<sup>15</sup> Sinclair. pg. 100

a continuous process, 2) it requires a PFR reactor as opposed to a continuous-stirred tank reactor (CSTR), 3) higher conversion, and 4) Aspen Plus is better able to model polymerization in the melt phase than in the aqueous phase. The main drawback to the melt phase process is higher operating pressures, which will require additional safety measures.

We have examined the market for nylon pellets and nylon fiber in addition to the resultant revenue. The market for nylon fiber is larger than that of thermoplastics, but the thermoplastics market is projected to grow at a higher rate. Spinning the product into a fiber increases capital and operating costs, but also increases the sale price. The additional equipment required for fiber production, such as spinnerets, also creates more safety hazards such as operating temperatures of over 300°C. Furthermore, the spinning process requires frequent human input to load and unload the bobbins, thus the spinning process necessitates the hire of additional employees in order to operate the process. Selling the product as pellets decreases capital and operating costs, but results in a lower sales price. However, according to the principles of inherently safer design, less equipment also creates safer operating conditions. In the interest of safety and process simplification, it was decided to sell the nylon product as pellets.

In order to maintain the high temperatures at which the process operates and to avoid contamination of the product, the entire nylon 6,6 manufacturing process must occur indoors. It is anticipated that a warehouse-like building will be constructed in which the manufacturing process will take place, the excess reactants and product will be stored, and the control room will be located. This warehouse should be well insulated so as to minimize the effects of ambient temperature, which historically has ranged anywhere from -9°F in the winter and 107°F in the summer.<sup>16</sup>

### **Design Approach**

The nylon production process was developed by first creating a simulation model with the chemical process simulation software Aspen Plus. Aspen Plus provided many advantages over hand calculations. The main advantages of using flowsheet simulation include bookkeeping of materials and energy, modeling complex physical interactions and phenomena, and iterative approaches using the power of the simulation engine. Disadvantages include difficulty for new users, inability to model unique unit operations, and the challenges inherent to the utilization of any rigorous simulation software.

---

<sup>16</sup> Intellicast. "Calvert City Historic Weather Averages in Kentucky." *Intellicast*. Web.

These disadvantages were acknowledged and appropriate steps were taken to ensure accuracy in the design. One example of this is the sizing approach used for R-01, the PFR used for the first stage of the polymerization. The kinetics of the condensation polymerization taking place in this unit are complex and dependent on parameters not taken into account with a simple power law reaction model for a single reaction. To address these complexities, a kinetic and equilibrium model derived from experimental data by Steppan et al. in “A Kinetic and Equilibrium Model for Nylon 6,6 Polymerization” was used alongside a common reaction engineering approach, the Levenspiel plot, in order to model and size the PFR using Microsoft Excel.<sup>17</sup> Averaged kinetic and equilibrium parameters were then applied to a simplified reaction model in Aspen Plus to validate the developed model.

When attempting to model the more specialized unit operations, adequate research was required to find techniques to size these specialized pieces of equipment. Manufacturer’s catalogues were also utilized as a “sanity check”. One example of this is the design and sizing of R-02, the wiped film evaporator. The unit was modeled as a continuous stirred tank (CSTR) in Aspen so the extent of reaction and processing volume could be approximated. Sizing of the evaporator was done by using techniques described in “Design of Wiped Film Evaporator (WFE) System with Recovery of Working Fluid for Herbal Products” by Vijaykumar Patel and Alkesh Mavani.<sup>18</sup> Once this was done, a manufacturer’s catalog for WFE’s was used to verify that the identified dimensions were appropriate.

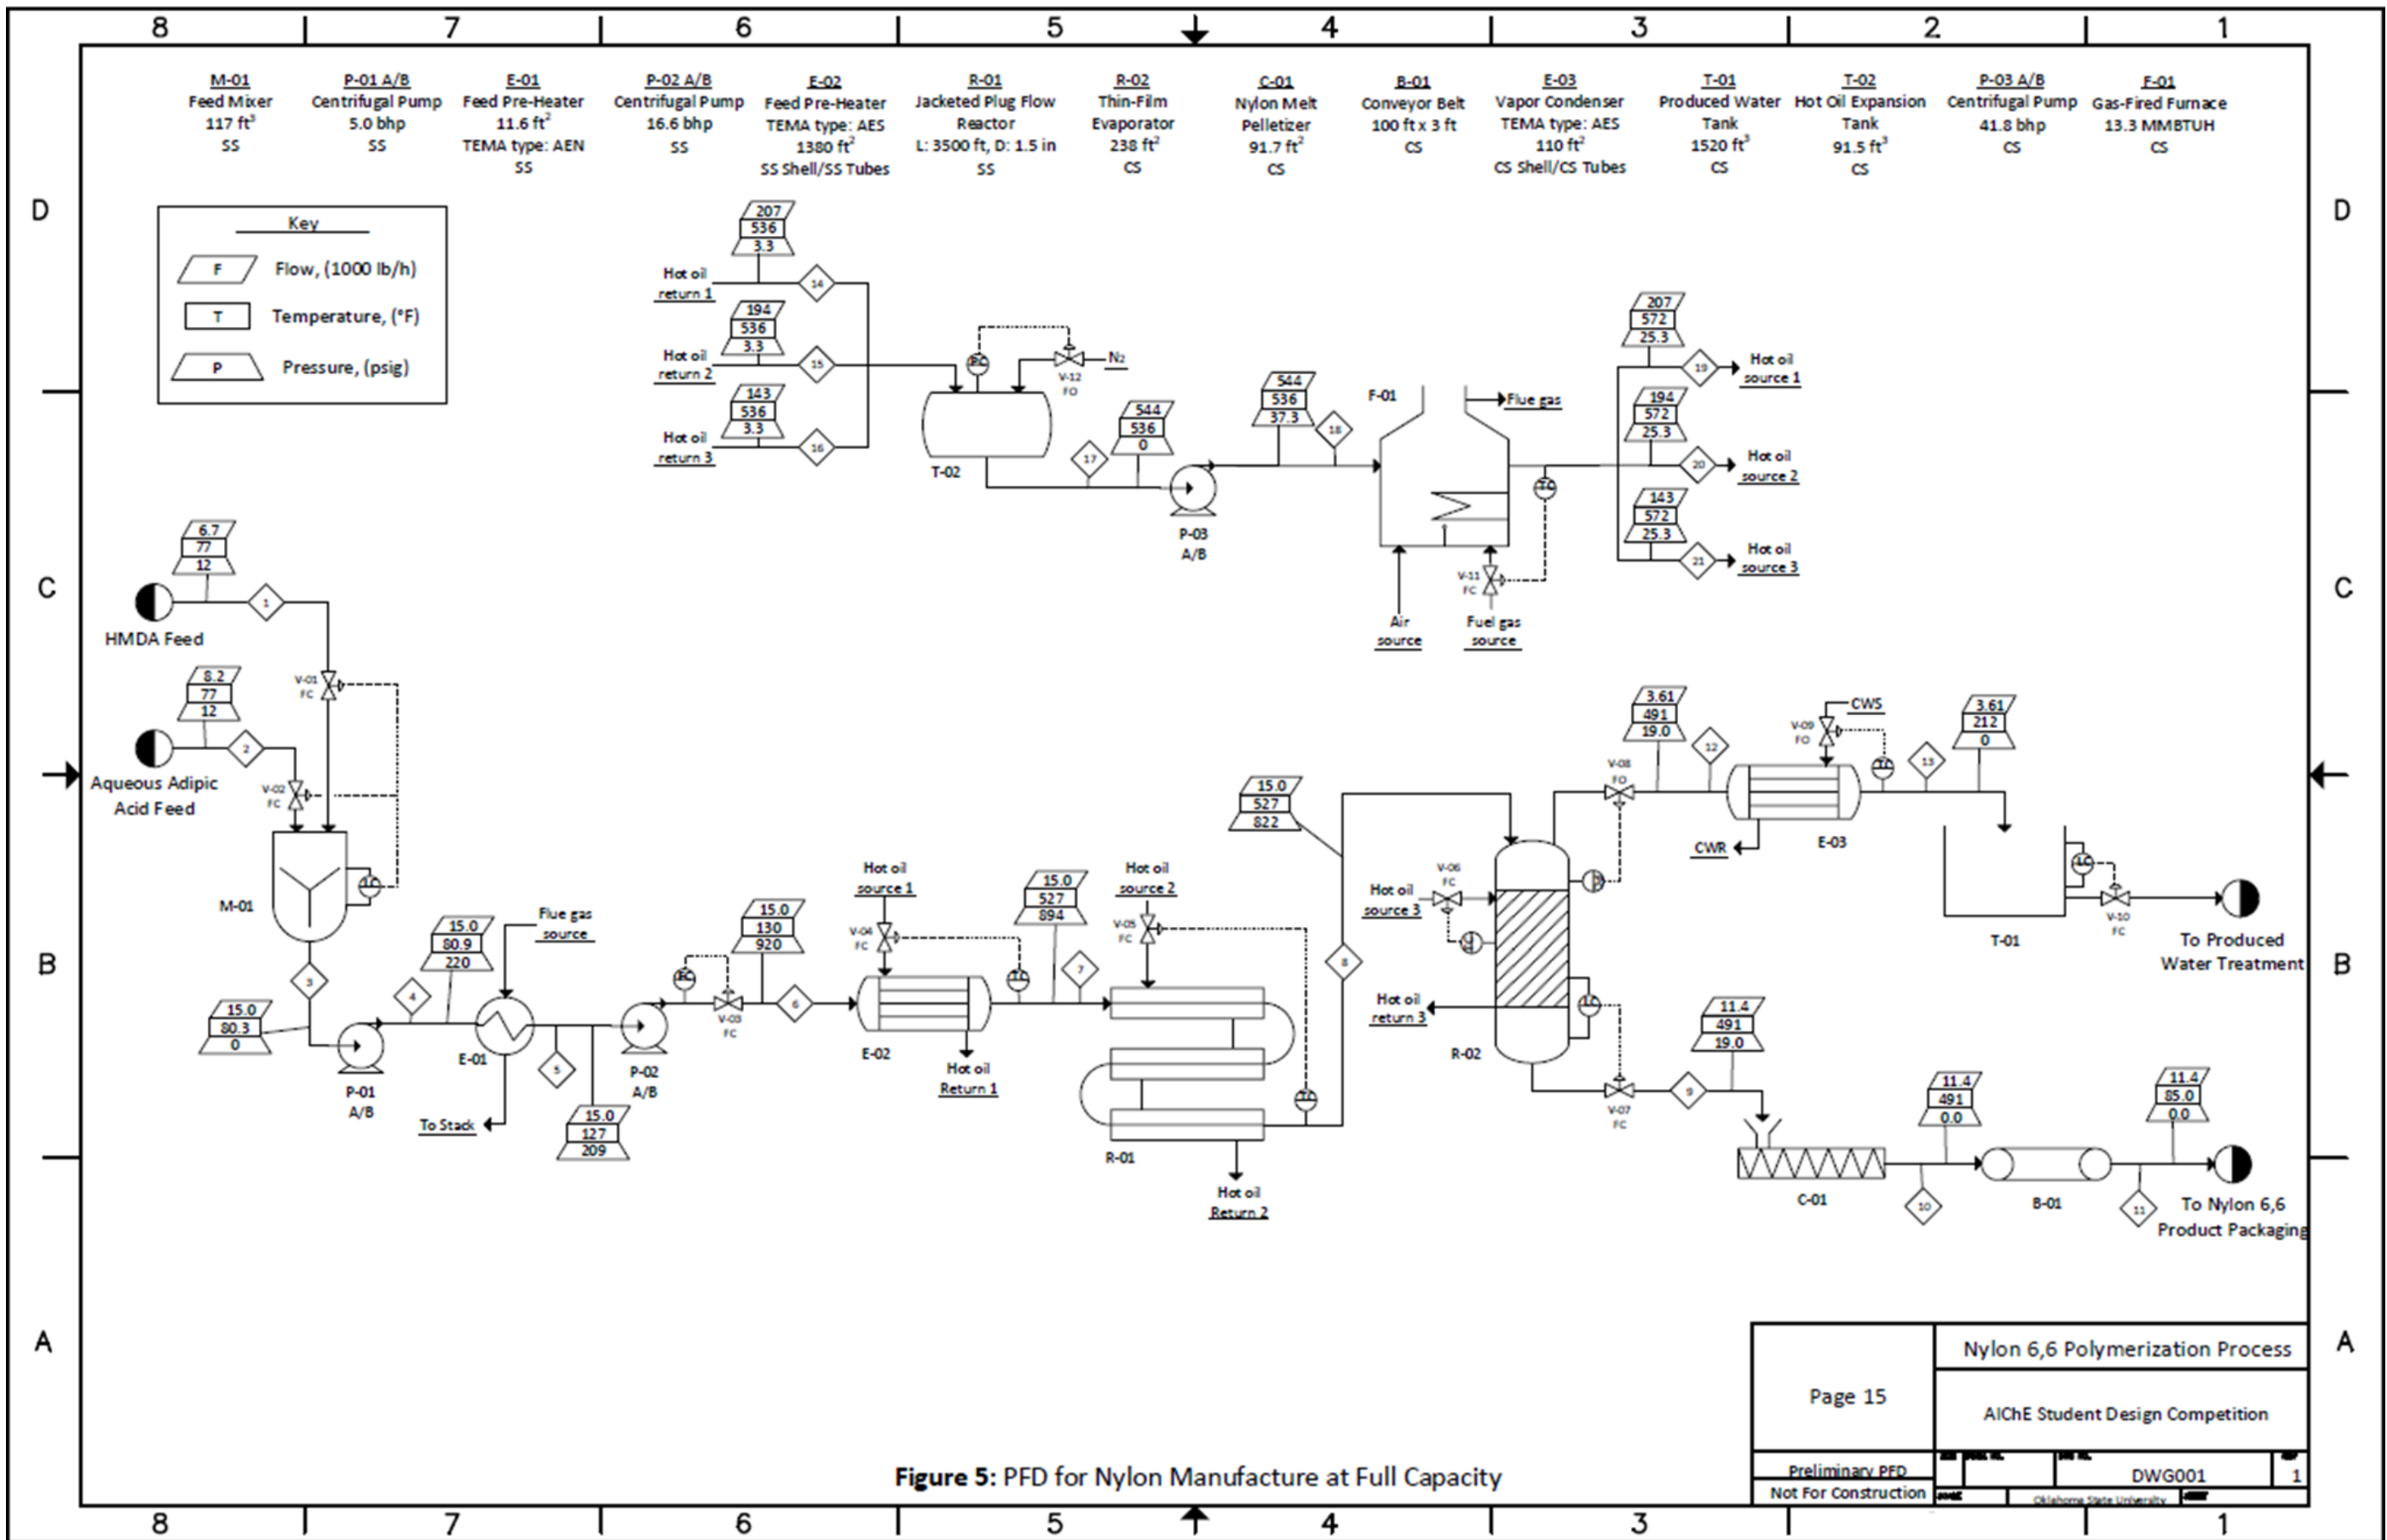

For most other process equipment sizing and design, Stephen Hall’s *Rules of Thumb for Chemical Engineers* was frequently referred to throughout the design of this process as it contains extensive heuristics tables and process approximations.

The PFD for the process at full capacity can be found in Figure 5 and the resultant stream table is in Table 5. The PFD for the 67% turndown case can be found in Figure 6 and the resultant stream table is in Table 6.

## Description of Process

As can be seen in the PFD for the process (Figure 5), HMDA and adipic acid for the process are shipped to the facility and stored in tanks (not shown) prior to being fed to the mixer, M-01, at atmospheric pressure and room temperature. From the mixer, the contents proceed to the first pump, P-01. P-01 is designed to increase the pressure of the reactant mixture from atmospheric to 220 psig. P-01 is able to handle a slight amount of undissolved solid which may be present in the solution after mixing. E-01 is downstream of P-01 and uses heat integration from the flue gas of F-01. E-01 is designed to increase the temperature to ensure that any leftover solid adipic acid dissolves. The reactant solution proceeds to the multi-stage pump, P-02 where the pressure is then increased to 920 psig. The preliminary design calls for four stages to P-02 in order to reach the desired pressure. A second heat exchanger, E-02, follows P-02 and utilizes a synthetic high temperature fluid (HTF) in order to heat the reactant solution to 527°F. After the system has reached 527°F, it is ready to enter the plug flow reactor, R-01. R-01 is jacketed because heat, also in the form of HTF, must be added for the reaction to proceed. R-01 is designed to be composed of 3,500 feet of 1.5-inch diameter pipe looped back and forth in order to reach the desired conversion over the 8.4 minutes that it takes fluid to pass through the reactor. The majority of the polymerization occurs in R-01 as above 90% of the nylon by mass produced by the process is polymerized in this first reactor. The average molecular weight of the nylon 6,6 leaving R-01 is 1,440 g/mol. Since nylon 6,6 is formed through a condensation polymerization reaction, water is a byproduct of the reaction. The newly formed nylon and the water byproduct flow towards the thin-film evaporator R-02, (sometimes referred to as wiped film evaporator or WFE) where the remainder of the polymerization occurs. Since the nylon solution has a pressure of 826 psig as it leaves R-01, it does not need to be pumped in order to reach R-02. The solution is flashed upon entry to R-02 in order to lower the solution pressure and separate the water from the nylon. The removal of water causes the reaction to proceed and the nylon will continue to make longer and longer chains. The thin film evaporator also relies upon HTF in order to keep the reactor at elevated temperatures to evaporate the water byproduct and prevent the nylon from freezing and fouling any lines or equipment. The evaporated water is then condensed in E-03 using cooling water before proceeding to T-01 where it is stored until a truck takes it to a produced water treatment plant. T-01 was designed with a holdup time of 1 day. The nylon 6,6 product exits out the bottom of the WFE and is then pelletized by C-01 and cooled and dried on conveyor belt B-01. It is then moved to nylon 6,6 product storage.

Duratherm S is the HTF chosen as a heat transfer medium in this process. Duratherm S was chosen over comparable synthetic hot oils because of its additives. The corrosion inhibitors, suspension agents, and metal deactivators are critical components in protecting the equipment from damage or blockage. It is also inherently safer than other oils because of its higher flashpoint. The HTF is stored in the expansion tank, T-02, where it is then pumped by P-03 to the fired heater, F-01. This fired heater uses fuel gas to heat the oil and send it to E-02, R-01, and R-02. The Duratherm is returned to T-02 after it has been utilized in these three locations.

### **Turndown Case**

In the instance of a decreased nylon 6,6 demand, the plant managers may want to reduce the overall nylon production to 67% of the typical plant production capacity. Clearly, the process equipment has been designed, sized, and optimized to run at full capacity. Thus, one of the main considerations is that only two-thirds of the volumetric flow that the equipment was sized for will be flowing through the process. The biggest concern is with the PFR, R-01. It was sized for a specific conversion at full capacity, so at lower capacities a higher conversion and molecular weight number (MWN) are reached. This is undesirable because if maximum conversion is reached, the nylon oligomer will react with itself (polycondensation), forming longer polymer chains. The larger and longer these chains become, the more viscous the nylon solution becomes, making it very difficult to pump and increasing the likelihood of line and equipment fouling. Furthermore, longer oligomer chains will be fed to the evaporator R-02, which will likely result in a nylon product that has a MWN that is above 20,000 g/mol. This is not ideal for most nylon 6,6 products, particularly those that will be spun and used for fabric. The best way to prevent this from occurring is to control temperature in R-02. If the temperature in R-02 is decreased, then water is vaporized at a slower rate, resulting in a slower polycondensation of the nylon to higher MWN product. It is recommended that in the future design steps that work be done towards developing a calibration curve relating exiting molecular weight to temperature of the WFE. The temperature of the unit will then be able to be adjusted conveniently depending on process demands. Doing this during the turndown case will limit the amount of hot oil flowing to the reactor so that approximately the same conversion and MWN is reached regardless of process operating volumetric flow rate. Thus, the turndown 67% capacity process should still be fed a proportional amount (67%) of feed materials, despite the fact that a higher conversion will be reached in R-01.

## Process Control

Table 7 below describes each of the control valves in the process. They can be found on the PFDs using the same nomenclature. Fail open or fail closed are safety mechanisms to minimize hazards such as runaway reactions, under pressurization, overheating, etc. Each control valve stem position (percent open) is based on a level, temperature, or pressure control sensor. As the set points are changed, the stem position on the corresponding valve will change to accommodate the set point. All descriptions in the table are based upon an emergency failure scenario.

**Table 7:** Description of Control Valves

<b>Control Valve</b>	<b>Fail Open or Fail Closed</b>	<b>Description</b>
V-01	Fail Closed	Fails closed to prevent process from initiating. Percent open adjusts based upon level control in M-01. Connected with a constant ratio to V-02.
V-02	Fail Closed	Fails closed to prevent process from initiating. Percent open adjusts based upon level control in M-01. Connected with a constant ratio to V-01
V-03	Fail Closed	Fails closed to prevent entrance to E-02. Percent open based upon flow control sensor downstream of P-01.
V-04	Fail Closed	Fails closed to prevent overheating. Percent open based on temperature control sensor of E-02 product stream.
V-05	Fail Closed	Fails closed to prevent overheating. Percent open based on temperature control sensor of R-01 product stream.
V-06	Fail Open	Fails closed to prevent overheating. Percent open based on temperature control sensor in thin-film evaporator.
V-07	Fail Closed	Fails closed to force toxic HDMA and ADA vapors into condenser. Percent open based on level control sensor on R-02 product stream.
V-08	Fail Open	Fails open to prevent over-pressurization of R-02. Percent open based on pressure control sensor on R-02.
V-09	Fail Open	Fails open to prevent overheating. Percent open based on temperature control sensor on E-03 product stream.
V-10	Fail Closed	Fails closed to prevent product from going to water treatment. Percent open based on level control sensor on T-01.
V-11	Fail Closed	Fails closed to prevent fuel gas from entering F-01. Percent open based on temperature control sensor on hot oil source line
V-12	Fail Open	Fails open to prevent vacuum formation and P-03 cavitation. Percent open based on pressure control sensor on T-02.

## Kinetic and Thermodynamic Parameters

Considerable effort was taken in modeling the condensation polymerization reaction occurring in the PFR, R-01. A single reaction rate constant was deemed inadequate to describe the complex system of reactions occurring in the PFR. It was decided that the best approach would be to model the reaction in Microsoft Excel using empirical relations found from established experiments. The Levenspiel plot technique (more information in “Equipment Lists, Sizing, and Selection”) could then be used to find the volume of reactor required. A reactor with appropriate dimensions could then be designed. These reactor dimensions were used to model the reactor in Aspen Plus software, using the averaged kinetic parameters developed in the Microsoft Excel model. The conversion output from Aspen Plus was found to be similar to the original conversion specified in the Excel model, thus validating the Aspen Plus in its ability to model this complex polymerization reaction.

Reaction kinetics were modeled based upon the work of Steppan et al., who developed an empirical equation describing the apparent 2<sup>nd</sup> order reaction rate constant as a function of water mole fraction.<sup>19</sup> Rates for the forward and reverse reaction are combined into a single rate. This is only valid when large stresses are not put on one side of the reversible chemical equation. This empirical model was utilized in the model developed in Excel. Each iteration of the model would calculate a new reaction rate constant based upon the new conditions. This reaction rate constant and the new concentrations of the reactants were used to find the reaction rate for that iteration. Approximately 500 iterations were performed for each PFR design to ensure precision.

Similar to reaction kinetics, thermodynamics influenced multiple aspects of design. The extent of polymerization in the first reactor is limited by thermodynamic equilibrium. The large operating pressure, while required to achieve the high rate of reaction needed for a continuous process, prevents any water from vaporizing. As the condensation polymerization reactions are reversible, the increase in water production leads to a shift in equilibrium away from the desired product, nylon 6,6. This is one of the main drivers for designing a second reaction stage. The agitated wiped film evaporator (WFE), is ideal for the second reaction stage because of its effectiveness in separating water from the R-01 product stream. As water is removed from the reaction system, equilibrium shifts towards the formation of more water and nylon 6,6. In the WFE there remains very little ADA and HMDA, so polycondensation, or growth of the polymer chains, takes place. Because Le Chatlier’s Principle influences the reaction in the WFE, it is important to consider both the forward and reverse

---

<sup>19</sup> Steppan, D. D., M. F. Doherty, and M. F. Malone. pg. 2335-2344

reactions explicitly. Kinetic data for this reaction set is given by Kevin Seavey and Y. Liu in *Step-growth Polymerization Process Modeling and Product Design*.<sup>20</sup> This results in a nylon 6,6 product with the molecular weight falling within the desired range (18,000 to 20,000 g/mol).

### Equipment Lists, Sizing, and Selection

The following tables include all of the equipment and some important specifications. Beneath each table is a detailed description of the equipment selection and sizing techniques. The spreadsheets attached in Appendix A show more detailed calculations of the values obtained in the tables below. Any equipment that encounters high concentrations of HDMA or adipic acid is constructed from stainless steel because these reactants are corrosive and thus incompatible with carbon steel. Equipment used for nylon 6,6, hot oil, or water uses carbon steel to lower capital costs.

The Duratherm HTF loop is required for heat exchange due to high process temperatures that are impossible to reach via high-pressure steam. The economics associated with this decision are discussed in the “Economic Analysis” section of this report.

**Table 8:** Process Vessel Details and Specifications

Vessels	Type	Volume (ft <sup>3</sup> )	Design Temperature (°F)	Design Pressure (psig)	MOC
M-01	Mixer	117	130	50	SS
T-01	Atmospheric Tank	1520	260	50	CS
T-02	Hot Oil Expansion Tank	165	590	55	CS

M-01 was sized as a horizontal process vessel with an impeller. It is assumed that the tank is well mixed. It is designed for a holdup time of 30 minutes. T-01 was sized to accommodate a holdup time of 1 day to allow for truck pickup and delivery of the water to a treatment facility. These holdup times should be sufficient in the case that something downstream results in a process bottleneck. T-02 was sized using expansion tank heuristics from Hall’s *Rules of Thumb for Chemical Engineers*. Using heuristics from Richard Turton et al. textbook *Analysis, Synthesis, and Design of Chemical Processes*, the volume of oil required to fill E-02 and R-01 was calculated. Dimensions of the WFE

<sup>20</sup> Seavey, Kevin, and Y. A. Liu. *Step-growth Polymerization Process Modeling and Product Design*. Hoboken, NJ: Wiley, 2008. Print. pg. 604-610

were compared to those of commercially available units to determine the volume of the jacket surrounding the unit. 100 feet of 7-inch diameter pipe between units was used to conservatively determine the volume of HTF in transit. Heuristics from Hall were used to calculate the normal liquid volume in the expansion tank and the total volume.

**Table 9:** Centrifugal Pump Details and Specifications

Centrifugal Pump	Efficiency (%)	Power (bhp)	Design Temperature (°F)	Design Pressure (psig)	MOC
P-01	75	5.0	130	270	SS
P-02	75	17	180	970	SS
P-03	75	42	590	90	CS

All three pumps were sized based upon differential pressure and flow rate requirements and typical pump efficiencies. The first pump provides adequate head so as to avoid vaporization of the feed when it is preheated in the economizer E-01. In the case that there are undissolved solids in the solution, it is recommended to use a radial impeller.<sup>21</sup> For this reason, P-01 utilizes a radial impeller to handle the excess solids. P-02 does not, and more importantly, it is a multistage pump with impellers in series. Multistage pumps are not recommended for liquids containing solids. This is why E-01, which will heat the solution and increase solid solubility, is located prior to P-02. This multistage configuration for P-02 is required because of the large amount of head that must be provided to the process fluid. The third pump serves as a recirculation pump for the hot oil used for heating throughout the process. P-03 requires a larger amount of power than the previous two pumps because of the high volumetric flow rate required for the hot oil loop.

The following pressure drops were assumed:

- 2 psi per 100ft of line including the PFR,
- 10-15 psi for control valves depending on flow rate,
- 10 psi for HTF fluid through equipment, and
- 9 psi for process fluid through equipment.

---

<sup>21</sup> Hall. pg. 102-117

Conservative efficiencies were assumed to be 75% for the pump and 80% for the motor. A high-pressure differential was designed for P-02 as the reactants need to be at a pressure of above 900 psig before entering R-01.

**Table 10:** Heat Exchanger Details and Specifications

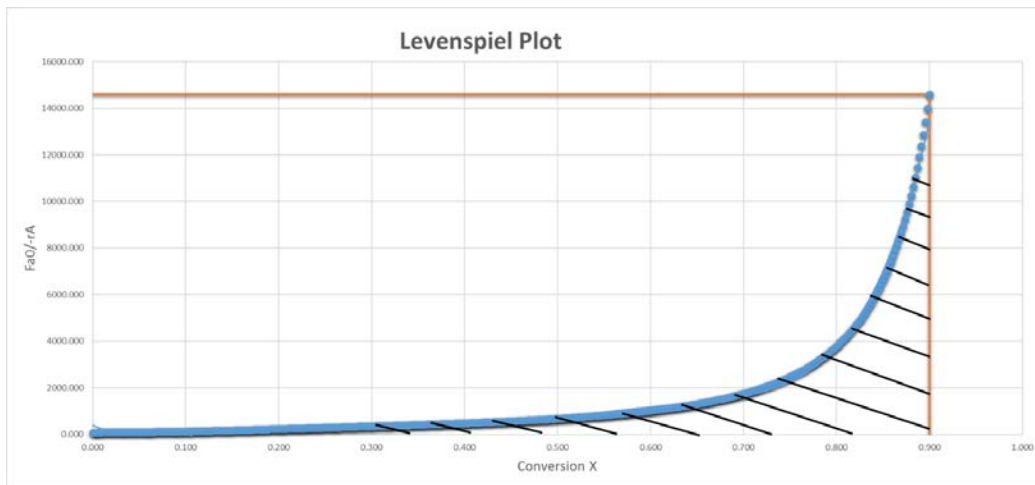

Heat Exchanger	Area (ft <sup>2</sup> )	Duty (MMBTUH)	Design Temperature (°F)	Design Pressure (psig)	MOC Shell/Tubes	TEMA Type
E-01	171	0.386	440	270	SS	AEN
E-02	541	3.95	620	970	SS	AES
E-03	110	-3.94	540	70	CS	AES

The placement of E-01 was chosen to reduce the amount of undissolved solids going through the high-pressure differential pump, P-02. The heat increases solubility of the ADA and HMDA, and the turbulent nature of flow provides mixing. This was necessary in order to protect the equipment from damage. Additionally, E-01 incorporates heat integration from the fired heater flue gas, making the process more efficient. For all three heat exchangers, necessary heat duties (Q) were taken from Aspen. These were then used to calculate heat exchanger area using typical overall heat transfer coefficient (U) values found in Turton et al. as well as the log mean temperature difference (LMTD). As mentioned before, stainless steel was used for E-01 and E-02 due to the corrosive nature of HDMA and adipic acid. An AEN heat exchanger type was utilized for E-01 because the temperature change of the process fluid is small enough for fixed tubes (46.8°F). Higher process fluid temperature changes in E-02 (397°F) and E-03 (279°F) require a floating head type (AES) in order to account for thermal expansion.

**Table 11:** Reactor Details and Specifications

Reactor	Type	Length (ft)	Diameter (in)	Area (ft <sup>2</sup> )	Design Temperature (°F)	Design Pressure (psig)	MOC
R-01	Jacketed PFR	3,500	1.5	N/A	580	945	SS
R-02	Thin-Film Evaporator	N/A	N/A	238	580	875	SS

Due to the positive order kinetics of this melt-phase polymerization reaction, a PFR is better suited than a CSTR for this process. This is shown below in the Levenspiel Plot generated from the Excel Model, shown below in Figure 7. In the Levenspiel plot technique, volume of the PFR reactor is found by integrating for the area under the reaction curve, shown by the diagonal black lines. The required volume for a CSTR to achieve the same conversion is found by calculating the area enclosed by the horizontal and vertical bars. To minimize capital investment, a PFR type reactor is the logical choice. The PFR, R-01, is simply a pipe with a jacket added in order to heat the tubular reactor to the desired temperature. This is almost exactly like a double pipe heat exchanger, thus R-01 has been sized as a double pipe heat exchanger.

**Figure 7:** Levenspiel plot used to determine type of reactor

It was observed that in a small PFR that low conversion was being achieved and resulting in the waste of unreacted feed materials. The tradeoff between the capital cost of the PFR versus the recurring cost of the raw materials was explored during design. Conversion was the variable connecting these two. A larger conversion required a larger reactor (higher capital cost), but lower raw material cost (recurring). Smaller conversion yields opposite effect. Ultimately, it was found that the price of raw materials had a much greater effect economically than the size of the reactor over a 10-year project life. So it was decided to increase reactor volume. The diameter of R-01 was sized based on a desired velocity of 4 - 8 ft/s. The length was then optimized to get high conversion at low cost. 90% conversion gives a feasible (albeit long) 3500-foot length with minimal unreacted products. However, because the diameter is only 1.5 inch, the PFR is able to snake back and forth while not taking up too much space and allowing for more efficient heating. R-01 was designed to withstand

temperatures over 550 °F and pressures over 900 psig. These high temperatures and pressures are necessary for the condensation polymerization reaction to proceed.

Wiped thin-film evaporators (WFEs) are preferred for high viscosity liquids, particularly when water is present. Thus, a WFE was chosen for the second reaction stage, R-02. The working principle of a WFE is that the thin film created by the agitator allows for the high heat flux that is required for water to overcome the relatively large activation energy for diffusion (58kJ/mol) in order for the water to evaporate nearly fully from the nylon product.<sup>22</sup> There is a low concentration of water in the nylon solution and a high concentration of water in the vapor leaving the WFE, thus significant energy is required to move the water against the concentration gradient. As water diffuses out and vaporizes, Le Chatlier's principle dictates that the condensation polymerization must proceed forward, driving the conversion and molecular weight up. It is important to note that any unreacted ADA and HMDA left with water out the vapor outlet, so no new short chain oligomers are formed in R-02.

The WFE diameter was sized based upon the desired water vapor flowrate of 6.5 ft/s<sup>23</sup> and the specified film thickness (0.5 in) of nylon 6,6 in the evaporator from Seavey and Liu.<sup>24</sup> R-02 is modeled as a CSTR in Aspen because a CSTR most closely resembles a thin-film evaporator. The Aspen model outputs a liquid volume and the WFE must have this same volume of liquid in it at a given time. Since the film thickness and diameter of the WFE is known, the cross sectional area of the liquid film is able to be calculated. This liquid film cross sectional area was used to calculate the heat transfer area. The height was found using the cross-sectional area and the liquid volume. Since the WFE was modeled as a CSTR in Aspen, the height of the design WFE was specified so that the volume of fluid in the design WFE matched the volume of fluid in the simulated CSTR. The process fluid was flashed into R-02 to lower the pressure, which aids in the evaporation process. Throttling valves were found to result in two-phase flow so flashing was seen as the better alternative.

Residence time in a WFE is generally short to protect the nylon product from excessive exposure to heat and potential thermal degradation. The residence time obtained in Aspen is not accurate because of the specified CSTR model. In a CSTR, most of the fluid is not in contact with the wall of the reactor, whereas in a WFE the surface area of fluid exposed to the heat flux is very large, thus the residence time should be much shorter for the reasons mentioned above.

**Table 12: Fired Heater Details and Specifications**

Fired Heater	Firing Rate (MMBTU/hr)	Design Temperature (°F)	Design Pressure (psig)	MOC
F-01	13.3	800	90	CS

The steps taken to find the heat duty for the process can be found below. The volume of Duratherm S required to fill the three units, transfer piping, and expansion tank were calculated. The required mass flow rate needed to achieve the desired heat transfer in each of the units was calculated using the Aspen simulation and the properties of Duratherm S from the Duratherm Heat Transfer Fluids website. The recirculating pump was sized by noting the pressure drops that occur through each vessel and through the connecting process lines. According to the recommendation from Hall's textbook, the pressure of the expansion vessel was set at 16 psia, which is 15 psi above the vapor pressure of the heat transfer fluid. The total required duty to heat the Duratherm S from 536°F degrees (estimated temperature inside the expansion tank) to 572°F was used to size and cost the fired heater. The duty provided by the fired heater was approximated by dividing the total required process duty by the thermal efficiency of a typical fired heater (0.78).<sup>25</sup>

As a measure of heat integration, the flue gas from the heater is used to preheat the process feed. From the heater efficiency, the flue gas temperature was estimated to be 200°C.<sup>26</sup> A typical heat capacity for flue gas was used to estimate the amount of heat transferred to the process for a given temperature change of flue gas. Combustion calculations, along with mass and volume flow approximations of flue gas can be found in Appendices A and C.

**Table 13: Miscellaneous Equipment Details and Specifications**

Other Equipment	Type	Width (ft)	Length (ft)	Area (ft <sup>2</sup> )	Design Temperature (°F)	Design Pressure (psig)	MOC
C-01	Nylon Melt Pelletizer	1.1	26.4	91.2	541	69	CS
B-01	Conveyor Belt	3	100	300	135	50	CS

<sup>25</sup> Turton et al. pg. 395

<sup>26</sup> Hall. pg. 169

The nylon 6,6 melt pelletizer, C-01, was sized using a graph from extrusionists.com.<sup>27</sup> The melt is fed to C-01 where a screw pushes it through an extruder where a blade cuts the melt into pellets. These pellets then fall to conveyor belt, B-01 for cooling. Other manufacturing possibilities exist such as spinning the nylon 6,6. It was found that a melt pelletizer is inherently safer because it is less complex, and it does not regularly require an operator to load the fiber onto a spinneret. The flowrate was extrapolated and a corresponding diameter was found for C-01. An industry heuristic from the aforementioned source was then used to find the length. B-01, was designed for a 1-inch depth of pellets on the belt. The area required was calculated based upon the cooling time, belt velocity, and the volumetric flowrate of the pellets.

## **SAFETY, HEALTH, AND ENVIRONMENTAL CONSIDERATIONS**

---

### **Safety Concerns**

A prerequisite for the process design is the safety of people, the environment, and the process equipment. The health and safety of all employees and citizens in the vicinity of the grassroots manufacturing facility is paramount. Compliance with the Occupational Safety and Health Administration's (OSHA) Process Safety Management (PSM) is mandatory for the process facility due to high quantities of adipic acid and HMDA.<sup>28</sup> According to the OSHA Process Safety Management Guidelines, "process safety management is the proactive identification, evaluation, and mitigation or prevention of chemical releases that could occur as a result of failures in processes, procedure, or equipment".<sup>29</sup> In order to maintain compliance with OSHA's PSM, companies are required to identify and control hazards and train their workforce how to properly operate equipment, be mindful of abnormalities, and handle emergencies. Information compiled in the PSM is also important for contractors working with the process, those performing the process start-up, insurance and enforcement officials, and emergency preparedness personnel.

A preliminary Process Hazard Analysis (PHA) has been completed in an attempt to identify, evaluate, and mitigate the hazards associated with the polymerization and pelletizing of nylon. The main

<sup>28</sup> Hall, Stephen. *Rules of Thumb for Chemical Engineers*. 2012. pg. 322

<sup>29</sup> U.S. Department of Labor. OSHA. *Process Safety Management Guidelines for Compliance*. 1994. Web.

hazards that have been identified include high operating pressures, high operating temperatures, chemical hazards, and loss of containment due to internal defects or to external factors.

### High Pressures

High-pressures may be found at the discharge of P-02, throughout R-01, and in the pipes prior to R-02. In R-02, the high pressure solution is flashed in order to reduce pressure and aid in water separation. All lines, process vessels, and reactors have been designed to withstand pressures of 50 psig above the normal operating pressures, but this is not sufficient pressure control. All process vessels are equipped with pressure relief valves that vent high-pressure vapors to a flare with a knock-out drum for nylon because it releases a toxic smoke when burned. Routine inspection and proper maintenance will minimize fouling through these valves.<sup>30</sup> Pressure imbalances for any reason can result in backflow and result in high pressures in unexpected areas, thus check valves should be installed and process lines should be properly instrumented to detect conditions that indicate backflow.<sup>31</sup> Furthermore, should these pressure relief valves be needed, it is important that all personnel are wearing proper ear protection as rupture causes damaging levels of noise.

### High Temperatures

Elevated temperatures are found throughout the process in order to result in melt-phase polymerization of nylon. In particular, the reactors and HTF loop are maintained at temperatures above 500°F. After the nylon is formed, high temperatures must be maintained to keep the nylon in the molten state. If the nylon freezes, it can foul lines and equipment, posing a large hazard to the process. All lines and process vessels are to be insulated. This helps to reduce heat loss to the environment and serves as a first line of protection for personnel against burns. The WFE is very sensitive to pressure changes. For this reason, special care should be taken by the control engineers involved in the detailed design process. Operators should be adequately trained to deal with changes in the process temperatures, especially as they concern the WFE. All personnel should wear burn protection gloves and long sleeves.

<sup>31</sup> Hall. pg. 328-331

## Chemical Hazards

It is important to understand the chemicals in the process and the risk they pose to health, safety, equipment, and the environment. Safety data sheets (SDS) have been referenced to collect the following hazards associated with the chemicals in this process:

**Table 14:** Chemical Hazards

<b>Component</b>	<b>Hazards according to SDS</b>
Adipic acid	Corrosive, causes serious eye damage, harmful to aquatic life, thermal decomposition can lead to release of irritating gases and vapors, combustible dust <sup>32</sup>
Hexamethylenediamine (HMDA)	Corrosive, causes severe eye and skin burns, causes digestive and respiratory tract burns, thermal decomposition can lead to release of irritating gases and vapors <sup>33</sup>
Nylon 6,6	Can burn in fire with dense toxic smoke, avoid breathing vapors or mist, molten plastic may cause severe burns, relatively stable in solid form <sup>34</sup>
Duratherm S (HTF)	Non-regulated material, avoid release to environment, flash point: 324°C, autoignition temperature: 437°C <sup>35</sup>

Due to the fact that adipic acid and HMDA cause serious eye damage, all personnel are required to wear protective eyewear. Since adipic acid dust is combustible and HMDA causes skin, respiratory tract, and digestive tract burns, personnel are required to wear protective and fire-resistant clothing.

## Fire Hazards

Nylon 6,6 is flammable and adipic acid dust is highly combustible, indicating the need for design elements to prevent fires and, in the case that fire does occur, control it. Three elements are required for combustion: oxygen, a fuel source, and a source of ignition. These three elements are commonly referred to as the “fire triangle”. If only one of these elements is taken away, combustion cannot occur. Any chemical in the process system (with the exception of water) could be a fuel source for a fire.

<sup>32</sup> Fisher Science Education. “Adipic Acid Material Safety Data Sheet (MSDS).” 20 Jan. 2015. Web.

<sup>33</sup> Fisher Science Education. “Hexamethylenediamine Material Safety Data Sheet (MSDS).” (2014): n.pag. *Fisher Scientific*. 24 Jan. 2014. Web. 27 Feb. 2017.

<sup>34</sup> Edinburgh Plastics, Inc. “Material Safety Data Sheet.” *Plastics Design*. 2 Oct. 2007. Web.

<sup>35</sup> “Duratherm S.” *Duratherm Heat Transfer Fluids*. Duratherm, 20 Dec. 2016. Web.

Common ignition sources include but are not limited to a spark, electrical arc, cigarette, static discharge, or a hot piece of equipment. Although the process equipment will be purged with nitrogen during start-up and the process is designed to avoid oxygen contamination, according to Nicholas Cheremisinoff in *Responsible Care*, controlling the source of ignition is often the easiest and safest way to avoid combustion. It is recommended that all unnecessary heat sources be turned off and sources of static electricity, such as cell phones, be left in cars and away from the operating area. In the case that a fire does occur, it is recommended to emergency shutdown all heat, electrical, and fuel sources. A water sprinkler system will be installed for the purpose of putting out fires by limiting heat.<sup>36</sup>

### Loss of containment

All efforts will be made to avoid loss of containment. Most emissions in chemical systems are a result of storage vessel filling and emptying. Since the process feeds are relatively stable in the aqueous phase, they can be stored in open tanks inside the process warehouse. Because the process will be indoors, loss of containment via loading and unloading of storage vessels will be mitigated. In order to prevent loss of containment elsewhere in the process, pumps are to have mechanical seals at the point of contact between the moving shafts and the stationary casing to prevent leakage or emissions. Liquid and vapor leaks can occur at any pipe flange or valve. This emission is reduced through regular inspection and proper maintenance.<sup>37</sup> In the case of large-scale loss of containment, the process should be quickly shut down and/or isolation valves be closed to isolate the area with emissions in order to minimize losses and contamination. The process will be indoors and as such will have proper ventilation systems including fume hoods and exhaust fans. Should loss of containment take place, the gases will be discharged safely through these additions. Furthermore, the emergency preparedness plan must be clearly communicated with all emergency response crews and personnel.

### Other Potential Hazards

One potential hazard could be overheating the process fluid. If for some reason the flowrate is slowed or halted, the amount of heat transfer to the process fluid will increase and could potentially overheat. This risk is mitigated through the use of controls on all heat transfer systems as described previously. Overheating could cause damage to the equipment and maybe even loss of containment.

---

<sup>36</sup> Cheremisinoff, Rosenfeld, and Davletshin. pg. 247-253

<sup>37</sup> Hall. pg. 334-336

This is also true for the Duratherm S HTF. For loss of flow, a switch is in place to shut down F-01 in order to prevent overheating. The sensors on flowrates are extremely important to prevent this from happening. The amount of cooling water, HTF, or flue gas used correlates to the amount of process fluid going through the system. There is also an inherent risk with using Duratherm S as a heating medium. As mentioned before, Duratherm S was chosen over other oils because of its higher flashpoint; however, leaks could result in fire. Once exposed to air, the hot oil may smoke a little as it is being oxidized. This is not the biggest danger though. It is important to use nonporous insulation near areas such as valves and flanges which are prone to leaks. Porous insulation such as mineral wool or fiberglass will absorb the oil and leave it unreacted with oxygen. This unreacted oil poses a catastrophic risk as it has the potential to burst into flames if the oxygen supply were to abruptly increase. Furthermore, it is necessary to provide suitable ventilation at all times so unreacted vapor is not accumulating in the event of low volume leaks. Finally, it is important to regularly perform fluid analysis to check for oxidation or contamination of Duratherm S.<sup>38</sup> Duratherm Heat Transfer Fluids will do used oil analysis on the system annually upon request.

#### Startup and Shutdown Considerations

Exact startup and shutdown instructions are beyond the scope of this project; however, there are a few important things to mention. Initially, the process fluid will be too viscous to reach its target flow rate. Because of this, it is important to gradually heat the process fluid. At slower flow rates it is easy to overheat the process fluid and damage the equipment due to the increased heat transfer. Damage of the equipment can be very dangerous and very costly. Damaged equipment can cause loss of containment, which is dangerous with process fluids of such high temperature and pressure. Therefore, during startup it is necessary to gradually increase the applied heat until the flow rate has increased to full capacity.

When shutting down, it is necessary to turn off the heat exchangers before the pumps to allow cooling to take place. This avoids damage to the equipment because this prevents the hot fluid from being trapped in the system and thermally degrading the equipment.

#### **Environmental Concerns**

Environmental aspect (EA) refers to the issues that a management needs to address for a process including public safety, worker protection, property damage, compliance, emissions, and waste

---

<sup>38</sup>"10 Tips: Hot Oil Systems." *Industrial Thermal Fluid Heating*. Process Heating RSS. Web.

management. An environmental management system (EMS) is a list of prioritized EAs for a particular business or industry and the plan to address these issues. The International Standards Organization (ISO) standard 14001 is commonly used to “find a common basis for managing the environment affected by a business’s operations”. According to ISO 14001, the most significant EAs to consider for a business’s EMS are emissions to air, waste management, releases to water bodies, contamination of land, and use of raw materials and natural resources.<sup>39</sup>

As for the project, nylon 6,6 itself is not very reactive and also not very harmful. However, it is very difficult to recycle or repurpose. Furthermore, if burned, it produces hazardous smoke containing hydrogen cyanide and nitrous oxide.<sup>40</sup> Making the monomer, adipic acid, has a significant impact on the environment because it produces nitrous oxide. Although the design does not include manufacturing the adipic acid, by buying this reactant it will still increase the amount of nitrous oxide introduced into the atmosphere. Nitrous oxide is a greenhouse gas that is 310 times more potent than carbon dioxide and is a major cause of climate change.<sup>41</sup> As of 1991, the production of nylon, and the subsequent production of nitrous oxide, has accounted for 10% of the increase in the atmospheric N<sub>2</sub>O.

### Emissions to Air

In order to minimize any emissions to air, plans have been made to equip all process equipment with pressure relief valves that vent to a flare system which includes a knock-out drum to prevent nylon from being burned. It is anticipated that the flare system will only be utilized in cases of over-pressurization or in an emergency. Pumps are designed to have mechanical seals. Regular inspection of all valves and flanges is recommended. Fired heater, F-01, will produce some carbon emissions as it requires fuel gas. From hand calculations, it was found that the emissions meet environmental standards. Additionally, the flue gas is repurposed as a heating source for E-01 before going out the stack.

### Waste Management

In order to optimize this project from an economics standpoint, conversion was varied in order to find the optimal PFR reactor size and volume of raw materials. As conversion increases, reactor size increases, but less raw materials are needed in order to achieve the desired nylon 6,6 molecular

---

<sup>39</sup> Cheremisinoff, Rosenfeld, and Davletshin. pg. 1-5

<sup>40</sup> Anne, Patty and Anne, Leigh. <https://oecotextiles.wordpress.com/2012/06/05/nylon-6-and-nylon-66/>

<sup>41</sup> “Nitrous Oxide” <http://apps.sepa.org.uk/sripa/Pages/SubstanceInformation.aspx?pid=8>

weight. As conversion decreases, reactor size decreases, but more raw materials are needed and thus more waste is produced. The leftover reactants cannot be recycled in the process; that would be like trying to un-bake a cake. A produced water solution will be separated from the nylon solution in the wiped-wall thin film evaporator. This produced water solution will be sent to a treatment facility.

#### Releases to Water Bodies

All cooling water output from the process heat exchangers will be monitored to ensure no nylon or reactant presence. The facility will recycle all cooling water and only release water once the EPA requirements are met.

#### Contamination of Land

The creation of containment troughs around the processing facility is recommended in order to prevent potentially-contaminated rainwater and other drainage from escaping into the Calvert City drainage system or the nearby river.

#### Use of Raw Materials and Natural Resources

A high volume of adipic acid and HMDA are utilized for this process. These raw materials are almost exclusively used to make nylon. The process utilizes a synthetic HTF, Duratherm S. This fluid gets recycled and reused throughout the process. It is anticipated to have a 10-year life and Duratherm Heat Transfer Fluids will do a used oil analysis to help identify when it should be replaced. Additional energy and cooling water are needed for this process.

### **ECONOMIC ANALYSIS**

---

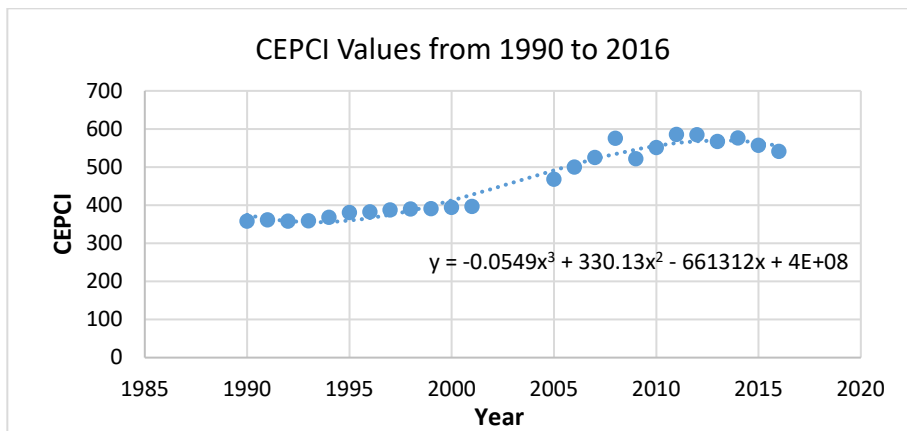

#### **Capital Cost Estimates**

As aforementioned, a hurdle rate or ROR of 15% and an effective tax rate of 40% is assumed. An assumption is made that 100% of the capital costs will be incurred in 2017 with production beginning in the subsequent year. A modified accelerated cost recovery system (MACRS) depreciation over 10 years is used based upon the United States tax code 13.3.<sup>42</sup> Turton et.al "Chapter 7: Estimation of Capital Costs" is used as a guide for the capital cost estimation. The process equipment estimates and values from this book are for US dollars in 2001, thus all values need to be escalated to US dollars in 2017, which is year 0 for the economic analysis. This is done using the Chemical Engineering Plant

---

<sup>42</sup> "Publication 946, How To Depreciate Property." IRS. Web.

Cost Index (CEPCI).<sup>43</sup> By graphing all values from 1990 to 2016 and fitting the data with a polynomial trend line, the CEPCI value for 2017 (see Figure 8) is approximated. The polynomial trend line function predicted the 2017 CEPCI value to be 542.34.

**Figure 8:** Historical CEPCI Values

Using equations 14, 15, and 16, found in Appendix D, the grassroots cost, in 2017 dollars, was calculated for each piece of equipment in the process. The grassroots cost refers to a completely new facility in which construction is started on undeveloped land. Since the process is beginning on from essentially ground zero, there are additional cost factors that are added in order to account for contingency and contractor fee costs and auxiliary facilities costs such as site development, auxiliary buildings, and off-sites and utilities.<sup>44</sup> The grassroots cost is calculated from the bare module cost via equations 15 and 16. The bare module cost takes into account the size, pressure, and materials of construction. Other variables are specific to each type of equipment and can be found in Turton et al. The sizing and costing variables for each piece of equipment can be found in Appendix A. The total capital costs associated with the proposed nylon 6,6 polymerization process can be found in Table 15. Please note that a backup pump has been included for each required pump in the process.

Table 15 shows the estimated capital costs for the process. The capital costs are the same for both the full capacity and turn-down case, as the process equipment remains unchanged regardless of the volumetric flow rate. The spreadsheets attached in Appendix A show more detailed cost calculations.

<sup>43</sup> "Economic Indicators - CEPCI." *Chemical Engineering*. Oct. 2016. Web.

<sup>44</sup> Turton, pg. 175, 193

**Table 15: Capital Costs**

<b>Equipment</b>	<b>Capital Costs</b>
M-01 (Mixer)	\$74,000
P-01 (Centrifugal Pump 1)	\$67,900
E-01 (Economizer)	\$201,500
P-02 (Centrifugal Pump 2)	\$132,200
E-02 (Feed Heater)	\$290,400
R-01 (PFR)	\$66,600
R-02 (Thin-Film Evaporator)	\$875,800
E-03 (Condenser)	\$150,700
T-01 (Water Holdup)	\$185,500
C-01 (Screw Conveyor)	\$42,900
B-01 (Belt conveyor)	\$247,700
P-03 (HTF Circulation Pump)	\$97,700
T-02 (HTF Expansion Tank)	\$50,500
HTF total	\$117,800
<b>TOTAL CAPITAL COSTS</b>	<b>\$2,258,000</b>

Please refer to Appendix A for exact costing and sizing for each piece of equipment.

### **Revenue and Operating Expense Estimates**

Revenue and operating expenses are both dependent on the amount of nylon 6,6 product produced by the process system. The assumed service factor is 0.90, which means that the process is on line for 90% of each year. The 10% of the year that the process is offline is used for routine maintenance, cleaning, and inspection. Although downtime reduces utility use and raw material costs, it also reduces total revenue. Furthermore, start-up can be quite challenging, so it is important to keep the process running as much as possible. Utility costs are assumed to be relatively constant from year-to-year based upon past data and long-term negotiations; however, uncertainty in the utility prices has been taken into account in the sensitivity analysis.<sup>45</sup> If there are any variations in the utility costs, it will be reflected in the nylon 6,6 sale price. The washout assumption was made for both raw material costs and in product revenue changes because the Consumer Price Index (CPI) and Producers Price Index (PPI) for polymers have been nearly constant since 1990.<sup>46</sup> All other annual costs were estimated using the following heuristics from Turton et al:

<sup>45</sup> "Electric Power Monthly with Data for August 2016." U.S. Energy Information Administration, Oct. 2016. Web.

<sup>46</sup> "Producer Price Index by Commodity for Rubber and Plastic Products." Federal Reserve Bank of St. Louis. Web.

- Maintenance is expected to be 4% of the fixed capital plant cost,
- Insurance is estimated to be 3.2% of the fixed capital plant cost,
- Plant overhead – the costs associated with operations of auxiliary facilities supporting the manufacturing process (i.e. accounting services, fire protection services, payroll and employee benefits, general engineering, etc.) – is estimated to be 70.8% of the labor cost and 3.6% of the fixed capital plant cost,
- Administration costs are estimated to be 17.7% of the labor cost and 0.9% of the fixed capital plant cost,
- Laboratory costs (to ensure quality control) are estimated to be 10% of the labor cost, and
- Operating supply costs and other miscellaneous expenses (i.e. lubricants, protective clothing, filters) are 0.9% of the fixed capital plant cost.<sup>47</sup>

Raw material costs were estimated using the quote provided by Invista. The amount of raw material required was estimated on the basis of 85 MMLb/yr of nylon 6,6 production with an assumed overall conversion of 90%. This assumption is based on the fact that the PFR was sized in the Excel model to achieve 90% conversion. Even if 90% conversion is not quite reached in the first stage, the evaporator will provide some additional conversion while driving up the molecular weight. Annual nylon 6,6 production rate and the expected annual revenue in 2017 dollars is given.

**Table 16:** Nylon 6,6 Yearly Production and Associated Revenue

<b>Flow</b>	<b>MMLb/yr</b>	<b>Annual Revenue</b>
Nylon 6,6 (full capacity)	89.7	\$ 106,000,000
Nylon 6,6 (67% capacity)	59.2	\$ 69,800,000

Required utilities include fuel gas for the fired heater F-01, electricity for the pumps, cooling water for the condenser E-03, and treatment for wastewater coming out of the condenser. Duty for each utility was calculated within the Aspen Plus simulation, and then the associated costs were estimated using prices from a Phillips 66 Design Project Statement.<sup>48</sup>

Table 17 below shows each utility and the cost per year. More detailed calculations of these values can be found in Appendix A.

<sup>47</sup> Turton, pg. 206

<sup>48</sup> Phillips 66, Oct. 21, 2016. *Proposed Ponca City Propylene Fractionation System* [Memorandum].

**Table 17: Annual Utility Costs**

<b>Utilities</b>	<b>Full Capacity Case (\$/yr)</b>	<b>Turndown Case (\$/yr)</b>
78% efficient Fuel Gas	397,600	262,300
Electricity	32,600	32,600
Cooling Water	24,900	16,400
Treatment	800	500
<b>TOTAL UTILITY COSTS</b>	<b>455,000</b>	<b>311,300</b>

Labor costs for operation were estimated as a function of unit operations (from procedure in Chapter 8.2 in Turton et al). A competitive salary of \$65,000 was estimated for each operator. Maintenance costs, incurred annually, were estimated to be 6% of the total capital investment.

**Table 18: Annual Cost of Labor**

<b>Cost of Operating Labor</b>		
<b>N<sub>np</sub></b>	6	# of equipment
<b>N<sub>OL</sub></b>	6.27	# of operators per shift
<b>N<sub>OLT</sub></b>	29	# of operators to cover 3 shifts
<b>W</b>	\$65,000	Wage average per 2080 hour year
<b>Operating Labor</b>	<b>\$1,885,000</b>	Operating labor/year

### **DCFROR Analysis**

A project hurdle rate of 15% was assumed for the project along with a 10 year project evaluation life. 10 year MACRS was used to depreciate equipment. Tax rate was assumed to be 40%. Since this is a grassroots plant, the grassroots factor from Turon et al was applied to all equipment costed. Equipment costs presented are grassroots costs (used costing factors from Turton). Production was assumed to start at the beginning of 2018. Table 19 below presents the findings of the analysis, which evaluated both the full production and turndown capacities.

**Table 19: Economic Analysis for Full-Capacity and Turndown Cases**

	<b>NPV (\$)</b>	<b>DCFROR</b>	<b>PWC</b>	<b>Payback Period</b>
<b>Full Capacity</b>	\$ 34,300,000	333%	\$ (2,370,666)	0.337 years
<b>Turndown Capacity</b>	\$ 20,300,000	212%	\$ (2,370,666)	0.514 years

A cash flow timeline was generated for the 10 year evaluation life for both the full capacity and turndown cases, which is shown below in Tables 20 and 21.

**Table 20: 10-year Cash Flow Table for Full Capacity Process**

<b>DCFROR=</b>	212%										

The plant is designed to be able to operate at turndown case, resulting in roughly 67% production capacity of nylon 6,6. To briefly examine the profitability of the plant in a constantly changing market, two hypothetical economic cases were considered.

For Case 1 the plant would operate at full capacity for the first 3 years, then at turndown capacity for the next 7 years due to a change in market demand of nylon 6,6. This would result in decreased sales revenue but with reduced raw material and utility costs for the process, but all other costs would remain the same. For Case 2 the plant would only operate at full capacity for the first operating year, then it would operate at turndown capacity for the remainder of the 10 year evaluation.

As expected, the NPV and DCFROR are still favorable. Results are shown in the Table 21 below.

**Table 22:** Hypothetical Case Economic Analysis

	<b>NPV (\$)</b>	<b>DCFROR</b>
<b>Case 1</b>	\$ 26,700,000	331%
<b>Case 2</b>	\$ 22,800,000	303%

### Sensitivity Analysis

A sensitivity analysis was done using tornado charts, all of which are shown below. Similar trends can be established between the full capacity and turndown cases for both the NPV and DCFROR analysis. Both operation situations yield a positive net present value, even when the worst case is considered.

**Figure 9:** Full Capacity NPV Tornado Chart

**Figure 10: Full Capacity DCFROR Tornado Chart**

Market conditions will play the largest role in the profitability of the process. As can be seen, a 2 percent price variation in raw material or nylon will have a much larger impact on the project NPV compared to a 25 percent variation in either capital or operating costs.

**Figure 11: Turndown NPV Tornado Chart**

**Figure 12: Turndown DCFROR Tornado Chart**

## CONCLUSIONS

---

Based upon this design, adipic acid and hexamethylenediamine are combined to produce nylon 6,6 pellets. This process was designed to meet the requirement that 85 million pounds of nylon 6,6 be produced annually. In fact, conservative sizing estimates were used such that the process is capable of producing 90 million pounds of nylon with a service factor of 0.90. The results shown in this report have been verified by Aspen Plus and vigorous hand calculations using Microsoft Excel as show in Appendix B.

The aforementioned economic analysis shows that the proposed process is quite profitable. Even in the 67% capacity turndown case, the NPV is positive. Evaluated over a 10-year project life, the full-scale process has an NPV of \$34,300,000, and the turndown case has an NPV of \$20,300,000.

## RECOMMENDATIONS

---

We suggest that this grassroots manufacturing plant be located in the industrial park in Calvert City, Kentucky. A 30-acre plot of undeveloped, unrestricted land located has been found at 150 Industrial Pkwy, Calvert City. The land is about a mile away from the Tennessee River and is posted for

\$80,000.<sup>49</sup> This plot of land is large enough for the process, extra storage, any necessary administration buildings, and employee parking. Furthermore, should the company expand into other manufacturing processes, there is enough land to do so.

In order to maintain the high temperatures at which the process operates and to avoid contamination of the product, the entire nylon 6,6 manufacturing process must occur indoors. It is anticipated that a warehouse-like building will be constructed in which the manufacturing process will take place, the excess reactants and product will be stored, and the control room will be located. This warehouse should be well-insulated so as to minimize the effects of ambient temperature, which historically has ranged anywhere from -9°F in the winter and 107°F in the summer.<sup>50</sup>

Further consideration should be taken for the produced water waste stream in the process. In the current design, this waste is sent to a water treatment facility and associated costs are considered. Moving forward, it may be beneficial to treat this water onsite and send it to the nearby river if the EPA standards can be met.

For the turndown case, changes may be necessary for the temperature set point on the WFE. Because a higher conversion is reached in the PFR, the molecular weight number of the nylon may be too high (above 20,000) exiting the WFE. This can be avoided by slightly lowering the temperature set point in the WFE. This will prevent the viscosity from becoming too high to finish the processing. This would require an empirical relationship between the amount of flow and the average molecular weight to be developed. If the viscosity can be measured directly, development of this empirical relationship can be avoided as the temperature would be lowered if the viscosity set point was exceeded.

The proposed process produces nylon chips. This design was chosen because it is inherently safer than the design for producing fiber due to the simplification from reduced equipment and steps. Furthermore, it requires less human input and allows us to hire fewer employees to run the process. If further evaluation finds that the reduced simplicity of the nylon fiber-spinning process is worth the additional revenue, the plant can be retrofitted with little effort.

<sup>50</sup> Intellicast. "Calvert City Historic Weather Averages in Kentucky." *Intellicast*. Web.

Based upon the conclusion of this report, it is the recommendation of the authors that the design of this process move from preliminary design to the detailed design phase.

## **ACKNOWLEDGEMENTS**

---

Several software and resources have been employed in order to complete this process. Due to its capabilities to model the series of complex reactions taking place during condensation polymerization, Aspen Plus has been utilized. Most calculations for capital and operating costs have been derived from Richard Turton's textbook *Analysis, Synthesis, and Design of Chemical Processes*. The equipment and sizing information has been documented in Microsoft Excel. The process PFDs and Piping and Instrumentation Diagrams (P&IDs) have been created using Microsoft Visio. All other resources can be found in the "References" section of this report.

## **Appendix B: Verification of Aspen PFR Simulation**

The spreadsheet on the following page is used to verify the estimated kinetic parameters used in the Aspen simulation. The Aspen results and the results from this sheet are different only to the degree of rounding error.

## Appendix C: Sample Calculations

The following tables show the formulas used in Excel to calculate the necessary values for costing and sizing. Many sizing and costing tables use the same formulas; therefore, representatives are shown here for each type of table. The far right column of each table is comments for various calculations.

	C	D	
3	<b>M-01</b>		Comments
4	Purchase Cost, Cp (2001)	=D5*D12*D16

## Appendix D: Equation List

### Heat exchanger design equations

$$5) \Delta T_{lm,counterflow} = \frac{(T_{h,i}-T_{c,o})-(T_{h,o}-T_{c,i})}{\ln\left(\frac{T_{h,i}-T_{c,o}}{T_{h,o}-T_{c,i}}\right)}$$

$\Delta T_{lm,counterflow}$  = Log mean temperature difference for a counter-current heat exchanger

$T_{h,i}, T_{h,o}$  = Inlet and outlet temperatures of hot stream

$T_{c,i}, T_{c,o}$  = Inlet and outlet temperatures of cold stream

$$7) q = U_o A \Delta T_{lm} \text{ (assuming subcooled liquid and saturated vapors)}$$

$q$  = Heat duty of heat exchanger

$U_o$  = Overall heat transfer coefficient of heat exchanger

$A$  = Area of heat exchanger

$\Delta T_{lm}$  = Log mean temperature difference of heat exchanger

### Capital cost equations

$$8) C_p = C_p^0 F_m F_p$$

$C_p$  = Actual purchased cost of specific equipment

$C_p^0$  = "Vanilla" (Carbon steel and 50 psig) purchased cost

$F_m$  = Material Cost factor

$F_p$  = Pressure Cost factor

$$9) \log_{10} C_p^0 = K_1 + K_2 \log_{10} A + K_3 [\log_{10} A]^2$$

$C_p^0$  = "Vanilla" (Carbon steel and 50 psig) purchased cost

$K_1, K_2, K_3$  = Equipment sizing factors from Turton Appendix A

$A$  = "Capacity" of equipment being sized

$$10) \log_{10} F_p = C_1 + C_2 \log_{10} P + C_3 [\log_{10} P]^2$$

$F_p$  = Pressure Cost factor

$C_1, C_2, C_3$  = Equipment pressure rating factors

$P$  = Design pressure of equipment

$$11) F_p = \frac{\frac{(P+1)^D}{2[850-0.6(P+1)]} + 0.00315}{0.0063}$$

$F_p$  = Pressure cost factor for a cylindrical process vessel

$P$  = Design pressure of vessel

$D$  = Diameter of vessel

$$12) F_{BM} = C_p^0(B_1 + B_2 F_M F_P)$$

$F_{BM}$  = Bare module cost factor – accounts for material of construction, design pressure, and installation costs

$C_p^0$  = “Vanilla” (Carbon steel and 50 psig) purchased cost

$B_1, B_2$  = Bare module factors – account for costs associated with installation

$F_M$  = Material Cost factor

$F_P$  = Pressure Cost factor

$$13) C_{BM} = C_p^0 F_{BM}$$

$C_{BM}$  = Bare module cost – Installed cost of specific equipment.

$C_p^0$  = “Vanilla” (Carbon steel and 50 psig) purchased cost

$F_{BM}$  = Bare module cost factor – accounts for material of construction, design pressure, and installation costs

$$14) C_{TM} = 1.18 C_{BM}$$

$C_{TM}$  = Total Module cost

$C_{BM}$  = Bare module cost

$$15) C_{BM}^0 = 3.29 C_p^0$$

$C_{BM}^0$  = “Vanilla” Bare module cost

$C_p^0$  = “Vanilla” (Carbon steel and 50 psig) purchased cost

$$15) C_{GR} = C_{TM} + .5 C_{BM}^0$$

$C_{GR}$  = Grass roots cost

$C_{TM}$  = Total Module cost

$C_{BM}^0$  = “Vanilla” Bare module cost

$$16) \text{Cost in Year A} = \text{Cost in Year B} \left[ \frac{\text{CEPCI in Year A}}{\text{CEPCI in Year B}} \right]$$

$CEPCI$  = Chemical engineering plant cost index – compares plant costs through time

### Operating cost equations

$$17) N_{OL} = (6.29 + 31.7P^2 + 0.23N_{NP})^{0.5}$$

$N_{OL}$  = Number of operators required per shift

$P$  = Number of processing steps involving particulate solids

$N_{NP}$  = Number of non-particulate processing steps (heating, cooling, mixing, etc.)

## Reaction Equations

$$18) k = Ae^{-E_a/RT}$$

$k$  = Reaction rate constant

$A$  = Pre-exponential Factor

$E_a$  = Activation Energy

$R$  = Universal Gas constant

$T$  = Absolute temperature

$$19) r = kC_A C_B$$

$r$  = Reaction Rate

$k$  = Reaction rate constant

$C_A$  = Concentration of A

$C_B$  = Concentration of B
