Organization Management
120 Wall Street
New York, NY 10005

Dear Organization Supervisor,
Enclosed is a completed preliminary design study of a grassroots facility to be built near Calvert City, Kentucky. This facility will produce 85 MM lbs/yr of Nylon 6,6 from adipic acid and HMDA. The process was designed for $100 \%$ as well as a $67 \%$ capacity turndown case. A number of simulations were designed, and an economic analysis was completed to determine the optimum process. A Hazard and Operability study (HAZOP) was completed in order to produce the safest design possible. The design group recommends proceeding with detailed design.

If you have any questions on these matters, please contact Rachel Davis at (479) 650-5134.
Sincerely,

Rachel Davis

#### Abstract

The purpose of this project was to develop a preliminary design of a grassroots plant for the production of nylon 6,6 near Calvert City, Kentucky. The yearly production rate of nylon 6,6 was specified at $85 \mathrm{MM} \mathrm{lbm} / \mathrm{yr}$. Nylon 6,6 is formed via a polycondensation reaction between adipic acid and hexamethylenediamine. Chains of nylon 6,6 lengthen via step-growth polymerization and the addition of new molecules to the end of each polymer chain.

The preliminary design for the grassroots process involves a pump, two heat exchangers, two reactors, a process vessel, an air cooler, and an extruder. The selected process involves a batch reactor in series with a CSTR in order to maximize polymerization and nylon 6,6 production. The design will produce nylon 6,6 chains with a degree of polymerization of 202. To produce the $85 \mathrm{MM} \mathrm{lbm} / \mathrm{yr}$ of nylon 6,6 , the design will require approximately 55.1 MM lbm of adipic acid, 43.9 MM lbm of HMDA, and 5.2 MM lbm of water each year for the reactants. The nylon 6,6 will be packaged and sold for $\$ 1.45$ per pound on average. Expected annual revenue for the grassroots plant is expected to be $\$ 123.3$ million in today's dollars. The design has a total capital investment of approximately $\$ 4.03$ million, including contingency, fees, and a grassroots factor. Manufacturing costs, including the costs for raw materials, are estimated to be $\$ 89.3$ million per year. Capital and manufacturing costs are estimated in today's dollars. The process was also designed for a $67 \%$ turndown case. This turndown case will cost $\$ 59.8$ million in manufacturing costs per year and has an expected annual revenue of $\$ 82.6$ million per year.

Economic evaluation over a ten-year period indicates that the design will have a net present value of $\$ 73.36$ million at a minimum rate of return of $15 \%$. The expected DCFROR is $5.17 \%$. Construction will begin in Quarter 4 of 2018, and startup is scheduled to take place on June 30, 2019. Upon evaluating the sensitivity, it was found that the sale price of nylon 6,6 has the largest effect on the economics of the design. The proposed design will require 8 plant operators in order to keep the unit running continuously and will cost $\$ 775,000$ in salary per year. Any safety risks have been accounted for, and a Hazard Operability study was completed.

The design team recommends proceeding with the detailed design phase for the grassroots facility. Equipment layout, including piping and elevation, will need to be completed in order to finalize the equipment sizing and designs. Several assumptions were made in the design process and in the estimation of costs. Therefore, a more thorough design and costing analysis should be completed in order to verify these assumptions during the detailed design.

## Introduction

The purpose of this project is to develop the plans for a grassroots plant for the production of nylon 6,6 in Calvert City, Kentucky. Nylon 6,6 was first synthesized in 1935 by Dupont Company [1]. It was the first truly synthetic fiber to be developed for a broad range of applications, and was quickly followed by nylon 6 [2]. Nylon 6,6 has found a wide range of applications due to its strength, stiffness, and heat resistance. Other advantages include its chemical resistance to hydrocarbons, wear resistance, and lubricity. The main limitations of nylon 6,6 include high water absorption and poor resistance to corrosion by strong acids and bases [3]. However, its many strengths have made it a material of interest for a wide variety of industries, particularly the textile industry [4]. It has applications in automotive parts, tubing, and piping, but approximately $75 \%$ of the nylon 6,6 produced in the United States goes into the manufacturing of home or clothing textiles [5]. From its initial inception, nylon has played a large role in the clothing industry. First developed as an alternative for silk stockings, it soon found its place in every type of clothing, leaving a noticeable mark on the industry. Today, it can be found in a wide variety of everyday items and has permeated the textile industry. In 2014, combined production of nylon 6,6 and nylon 6 topped 7.2 million tons, and the market continues to grow [6]. This combined polyamide market is currently estimated at 25.14 billion USD, with projections to grow to 30.76 billion USD in the next five years [7]. This market growth, combined with the growing uses for nylon 6,6 products, yields a convincing argument for the need to invest in new production facilities.

Nylon 6,6 is synthesized via a polycondensation reaction between hexamethylenediamine (HMDA) and adipic acid (ADA). HMDA is a diamine composed of a six-carbon chain with amino groups at each end [8]. Adipic acid is an organic compound consisting of a six-carbon chain with carboxylic acid groups at each end [9]. Nylon 6,6 itself has a monomeric formula of $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}_{2}$, and lengthens via step-growth polymerization and the addition of new molecules to each end of the polymer chain [10]. The overall reaction is shown below in Figure 1.

Figure 1: Overall Reaction for Nylon 6,6 Production [11]

Initially, the two reactants combine to form a nylon 6,6 salt with stoichiometric equivalents. The nylon salt is then sent to a reactor where the process of step-growth polymerization begins. Then, aqueous nylon 6,6 is sent to a second reactor where water is removed. The removal of
water drives the reaction to completion and leads to further lengthening of the polymer chain. Increased levels of water removal yield higher molecular-weight nylon. This molten nylon is then ready for further processing into pellets or fibers. The resulting water side stream can be treated and released.

Production will take place at a grassroots plant in the Calvert City, Kentucky area. The Calvert City area is home to a multitude of chemical processing plants of various sizes, offering a community familiar to interacting with processing plants. In addition, the presence of many chemical plants and refineries creates a sense of scientific community among the businesses in the area. At this time, the production rate has been specified at $85 \mathrm{MM} \mathrm{lbm} / \mathrm{year}$. This system has been designed for a full production case, as well as a turndown case of $67 \%$ capacity.

For this project, a two-reactor scheme has been developed. The first of the two reactors is a batch reactor, and the second is a CSTR. A block-flow diagram of this process can be seen below in Figure 2.

Figure 2: Block-Flow-Diagram for Batch/CSTR Process

This particular scheme was chosen for its economic attractiveness and the ability to develop a simple and effective safety strategy for the process. Also considered were PFR/CSTR and CSTR/CSTR reactor schemes. However, both schemes were rejected for this project. The CSTR/CSTR scheme yielded a nylon 6,6 product below the appropriate molecular weight and degree of polymerization specifications needed for sale. The PFR/CSTR scheme yielded highquality nylon 6,6 , but was less economically attractive, especially for the turndown case. In addition, the Batch/CSTR process allowed for a simpler safety strategy. These economic and safety factors are described in more detail in subsequent sections of this report.

In developing the plans for this nylon 6,6 production plant, a variety of environmental and safety factors were considered. The raw materials from this process, HMDA and adipic acid, can cause irritation to the skin and eyes upon contact. In addition, inhalation of dust from these materials can cause irritation of respiratory tracts. Both HMDA and adipic acid are slightly flammable, but only at elevated temperatures. Steps to mitigate these hazards were taken in order to reduce
the risk of exposure. Nylon 6,6 itself can also irritate the eyes or lungs, but it is not considered to be a major skin irritant. Thermal decomposition of nylon can lead to toxic vapors. Therefore, processes were kept at temperatures below the decomposition temperature of nylon 6,6. The water byproduct stream of the process must be put through wastewater treatment systems before being released to the environment in order to prevent the release of any remaining raw materials or product. A HAZOP analysis revealed the importance of controlling the temperature of the process, as well as maintaining the integrity of the streams. This project report and accompanying appendix will elaborate on the chosen process, as well as the equipment needed to execute the process. In addition, this report will investigate the economic and safety factors considered when developing this system and deciding on the final process design.

## Process Description

## Reactor Modeling:

For the purpose of this preliminary design, Aspen Plus was used to model the polymerization of nylon 6,6 in both reactors. A step-growth polymerization model was used in order to represent the addition of monomers to the polymer chain. This model includes 12 equations to account for the condensation reactions, as well as the addition of HMDA and ADA to the ends of the polymer chain. This model works by separating available HMDA and ADA into repeat units and end units. By separating these components, the model can differentiate between segments of the reactants available for polymerization. Figure 6, shown below, shows the components used in the reactor models, including their common names and structures.

| Model Name | Common Name | Trivial Formula | Molecular Structure |
| :---: | :---: | :---: | :---: |
| H2O | Water | $\mathrm{H}_{2} \mathrm{O}$ | H2O |
| HMDA | Hexamethylenediamine | $\mathrm{C}_{6} \mathrm{H}_{16} \mathrm{~N}_{2}$ |  |
| ADA | Adipic Acid | $\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{O}_{4}$ |  |
| HMDA-E | HMDA end | $\mathrm{C}_{6} \mathrm{H}_{15} \mathrm{~N}_{2}$ |  |
| ADA-E | ADA end | $\mathrm{C}_{6} \mathrm{H}_{9} \mathrm{O}_{3}$ |  |
| HMDA-R | HMDA repeat unit | $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{~N}_{2}$ |  |
| ADA-R | ADA repeat unit | $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{2}$ |  |
| NYLON66 | Nylon 6,6 | $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}_{2}$ |  |

Figure 6: Components Used in Reactor Model [12]
These components are combined in the model in order to accurately depict the process taking place in the reactor. The 12 unique reactions combine to form the overall reaction described by

Figure 1 in the Introduction section. Four reactions account for condensation, four equations account for polymerization, and four reactions account for reverse condensation. These 12 reactions can be seen below in Figure 7.

| Reaction Type | Reactants | $\Rightarrow$ | Products |
| :--- | :--- | :--- | :--- |
| Condensation | HMDA + ADA | $\Rightarrow$ | H2O + HMDA-E + ADA-E |
| Condensation | HMDA + ADA-E | $\Rightarrow$ | H2O + HMDA-E + ADA-R |
| Condensation | HMDA-E + ADA | $\Rightarrow$ | H2O + HMDA-R + ADA-E |
| Condensation | HMDA-E + ADA-E | HMA-R + ADA-R |  |
| Polymerization | HMDA + ADA-E + HMDA-R | $\Rightarrow$ | HMDA-E + HMDA-E + ADA-E |
| Polymerization | HMDA + ADA-R + HMDA-R | $\Rightarrow$ | HMDA-E + HMDA-E + ADA-R |
| Polymerization | HMDA-E + HMDA-E + ADA-E | $\Rightarrow$ | HMDA-R + ADA-E + HDMA |
| Polymerization | HMDA-E + HMDA-E + ADA-R | $\Rightarrow$ | HMDA-R + ADA-R + HMDA |
| Rev-Condensation | H2O + ADA-E + HMDA-E | $\Rightarrow$ | ADA + HMDA |
| Rev-Condensation | H2O + ADA-E + HMDA-R | $\Rightarrow$ | ADA + HMDA-E |
| Rev-Condensation | H2O + ADA-R + HMDA-E | $\Rightarrow$ | ADA-E + HMDA |
| Rev-Condensation | H2O + ADA-R + HMDA-R | $\Rightarrow$ | ADA-E + HMDA-E |

Figure 7: Model Reactions Used in Aspen Plus Simulation [12]

Forward reaction rate data was obtained using correlations described in Kumar, et. Al [13, 14] using data given by Ogata, et. al, 1961 [15, 16]. These correlations were deemed appropriate for this model because they accounted for the batch-style reactor used in the process. These correlations took into consideration the temperature of the reactor, as well as the presence of water in the feed stream. Because the process has a $99.92 \%$ conversion and is designed using conditions that result in effective removal of the majority of the water, the reaction is assumed to be irreversible. This assumption was made because the removal of water drives the reaction to the right far enough to neglect the reverse reaction. Rate constants for all considered cases are shown in Figure 8 below.

| Reactor: | Rate Constant: <br> $\left.\mathbf{f t t}^{\mathbf{3}} / \mathbf{l b m o l - h r}\right)$ |
| :--- | ---: |
| R-101 | 25200 |
| R-102 | 50.4 |

Figure 8: Rate Constant Data for All Cases

The rate of the reaction for Reactor R-101 is modeled by Equation [1] below.

$$
\begin{equation*}
r_{A}=k[A D A][H M D A] \exp \left(\frac{-2500}{R T}\right) \tag{1}
\end{equation*}
$$

Where $\mathrm{r}_{\mathrm{A}}=$ reaction rate, $\mathrm{lbmol} / \mathrm{ft}^{3}-\mathrm{hr}$.
$[\mathrm{ADA}]=$ concentration of adipic acid, $\mathrm{lbmol} / \mathrm{ft}^{3}$
[HMDA] = concentration of hexamethylenediamene, $\mathrm{lbmol} / \mathrm{ft}^{3}$
$\mathrm{R}=$ ideal gas constant, $\mathrm{J} / \mathrm{mol}-\mathrm{K}$
$T=$ reactor temperature, $K$
$\mathrm{k}=$ rate constant, $\mathrm{ft}^{3} / \mathrm{lbmol}-\mathrm{hr}$

The rate of the reaction for Reactor R-102 is modeled by Equation [2] below.

$$
\begin{equation*}
r_{A}=k\left[H_{2} O\right]^{2} \exp \left(\frac{-2500}{R T}\right) \tag{2}
\end{equation*}
$$

Where $\mathrm{r}_{\mathrm{A}}=$ reaction rate, $\mathrm{lbmol} / \mathrm{ft}^{3}-\mathrm{hr}$
$\left[\mathrm{H}_{2} \mathrm{O}\right]=$ concentration of water, $\mathrm{lbmol} / \mathrm{ft}^{3}$
$\mathrm{R}=$ ideal gas constant, $\mathrm{J} / \mathrm{mol}-\mathrm{K}$
$T=$ reactor temperature, $K$
$\mathrm{k}=$ rate constant, $\mathrm{ft}^{3} / \mathrm{lbmol}-\mathrm{hr}$

## Batch Process Description:

Figure 3 on Page 7 displays a full PFD for the chosen batch reactor process. In addition, stream summary tables for both a full capacity case and a $67 \%$ capacity turndown case can be found in Figure 4 on Page 8 and Figure 5 on Page 9, respectively. The process begins with the mixing of ADA (Stream 1) and HMDA (Stream 2) at a mixing valve (VLV-101 A/B) to form a mixed reactant stream (Stream 3). This stream is approximately $13.8 \mathrm{wt} \%$ water, and is the location of the beginning of the reaction to form the nylon 6,6 salt. The mixed feed stream is pressurized via $\mathrm{P}-101 \mathrm{~A} / \mathrm{B}$ and heated to $410^{\circ} \mathrm{F}$ via a steam-powered heat exchanger (E-101 A/B). This heated and pressurized feed is delivered to $\mathrm{R}-101 \mathrm{~A} / \mathrm{B} / \mathrm{C} . \mathrm{R}-101 \mathrm{~A} / \mathrm{B} / \mathrm{C}$ is a batch reactor heated with an electric jacket. In this reactor, the nylon salt/reactant mixture reacts further to form an aqueous nylon stream. This aqueous nylon mixture (Stream 7) is then sent to a holding tank (V$101 \mathrm{~A} / \mathrm{B}$ ) before entering a second reactor (R-102 A/B). A vent stream (Stream 6) allows for the removal of vapor from $\mathrm{R}-101 \mathrm{~A} / \mathrm{B} / \mathrm{C}$. In the second reactor ( $\mathrm{R}-102 \mathrm{~A} / \mathrm{B}$ ), the aqueous nylon mixture (Stream 8) is further heated in order to remove as much water as possible. The removal of water vapor via the vent stream (Stream 9) pushes the reaction to the right, thus lengthening the polymer chain and increasing the quality of the product. The vent stream (Stream 9) is
combined with the vent stream from R-101 A/B/C (Stream 6) at VLV-102 A/B and cooled to $100^{\circ} \mathrm{F}$ via E-102 A/B. This cooled combined vent water stream (Stream 12) is then sent through wastewater treatment and released. Heat integration was considered, but it was found that Stream 12 does not contain enough energy to be used to heat the feed stream. The molten nylon 6,6 stream (Stream 10) is then sent to an extruder to be pelletized and cooled via E-103 A/B before packaging and shipping. Due to the potential dust production and tendency of nylon 6,6 to degrade when exposed to water and heat, this plant was designed to send the finished pellets directly to packaging and shipping rather than to a storage container or vessel.

The process will require $55.1 \mathrm{MM} \mathrm{lbm} / \mathrm{yr}$ of ADA, $43.9 \mathrm{MM} \mathrm{lbm} / \mathrm{yr}$ of HMDA, and 5.2 MM $\mathrm{lbm} / \mathrm{yr}$ of feed water in order to produce the required $85 \mathrm{MM} \mathrm{lbm} / \mathrm{yr}$ of nylon 6,6 . The degree of polymerization will be approximately 202. Further details on individual pieces of equipment and reasons for equipment choices are discussed in the subsequent Equipment Lists and Equipment Specifications sections.

## Alternative Processes:

In addition to the chosen batch reactor process, an alternative reactor setup was also considered. This setup featured a plug-flow reactor as R-101 rather than a batch reactor, followed with a CSTR for R-102. A block-flow diagram for this process can be seen below in Figure 9.

Figure 9: Block-Flow Diagram of PFR/CSTR Process

A PFD for this process can be found in Figure 11 on Page 15. Stream Summary Tables for this alternative process can be found in Figure 12 on Page 16 for a full capacity case and Figure 13 on Page 17 for a $67 \%$ capacity turndown case. This process functions in a similar way to the original batch process, with the only difference being the replacement of the batch reactor with a plug-flow reactor. Though this process is a viable option, the batch process was found to be more economically attractive and an overall safer process than the PFR process. These points will be discussed further in this report in the Economic Analysis and Safety sections.

A third process was considered in initial research stages but was rejected early in the design process. This reactor scheme included two CSTRs in series to create the nylon 6,6 product.

Though this design could be economically attractive, it yields a much lower molecular weight product. This product is below the accepted degree of polymerization standards for nylon 6,6 and would not be of a high enough quality to sell for profit. A block-flow diagram of this process can be found below in Figure 10.

Figure 10: Block-Flow Diagram of CSTR/CSTR Process
The final Batch/CSTR process was chosen for its combination of economic attractiveness as determined by Net Present Value (NPV) incremental analysis and Discounted Cash Flow Rate of Return (DCFROR) comparison, as well as its ability to remain profitable under turndown conditions. In addition, this process has fewer inherent safety risks, and is thought to be the best choice for this plant. These points will be investigated in more detail throughout this report.

## Energy Balance and Utility Requirements

## Heat Exchangers:

As described in the previous section, this process design requires multiple heat exchangers in order to meet the necessary temperatures needed for reaction, wastewater treatment, and packaging. The first of these is Heater E-101, which is necessary to heat the nylon salt solution (Stream 4) to $410^{\circ} \mathrm{F}$. This temperature is below the temperature needed for the first reactor. It was found that if we heated the reactants too much prior to entering the reactor, we would have a reaction taking place in the piping. This would result in a blocked pipe and loss of conversion. Through a sensitivity analysis, we found that $410^{\circ} \mathrm{F}$ is the optimum temperature for Stream 4 prior to entering the reactor. This temperature maximizes conversion and minimizes energy costs.

High pressure steam is used as the heating agent because of its cost effectiveness. The heat requirement to heat Stream 4 from $141^{\circ} \mathrm{F}$ to $410^{\circ} \mathrm{F}$ is $2.34 \mathrm{MM} \mathrm{Btu} / \mathrm{hr}$. This value comes from the Aspen Plus simulation. High Pressure steam will provide the necessary heat duty needed to make this heat exchange work. The high pressure steam is condensing and thus does not undergo a temperature change. Using Equation [3], we are able to calculate the necessary steam flow rate to obtain the correct heat duty.

$$
\begin{equation*}
\dot{m}=\frac{Q}{\lambda} \tag{3}
\end{equation*}
$$

Where $\dot{\mathrm{m}}=$ steam flow rate, $\mathrm{lbmol} / \mathrm{hr}$
$\mathrm{Q}=$ heat duty, $\mathrm{Btu} / \mathrm{hr}$
$\lambda=$ latent heat of vaporization for high pressure steam (720 Btu/lbm at 600 psig [17])

From this equation, the steam flowrate has been calculated to be $3250 \mathrm{lbm} / \mathrm{hr}$.

Stream 11 is the combined water vent stream from both of the reactors. This stream is at a temperature of $363^{\circ} \mathrm{F}$ and is too high to allow for proper wastewater disposal. Thus, it will need to be cooled down. To meet these necessary requirements, the wastewater will be cooled down to $100^{\circ} \mathrm{F}$ [18]. This will take place in Cooler E-102. From the Aspen Plus simulation, Stream 11 will have to release $4.08 \mathrm{MM} \mathrm{Btu} / \mathrm{hr}$ of heat for the wastewater stream to be cooled from $363{ }^{\circ} \mathrm{F}$ to $100^{\circ} \mathrm{F}$. Cooling water at $87^{\circ} \mathrm{F}$ will absorb the 4.08 MM Btu/hr of heat and will subsequently increase its temperature to $100^{\circ} \mathrm{F}$. The amount of cooling water required to transfer this heat duty can be calculated by Equation [4].

$$
\begin{equation*}
Q=\dot{m} C_{p} \Delta T \tag{4}
\end{equation*}
$$

Where: $\mathrm{Q}=$ heat duty, Btu/hr
$\dot{\mathrm{m}}=$ mass flow rate of cooling water, $\mathrm{lbm} / \mathrm{hr}$
$\mathrm{C}_{\mathrm{p}}=$ average heat capacity, $\mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F}$
$\Delta \mathrm{T}=$ change in cooling water temperature, ${ }^{\circ} \mathrm{F}$

Using an average temperature of $93.5^{\circ} \mathrm{F}$, the heat capacity of water is equal to $1.01 \mathrm{Btu} /\left(\mathrm{lb}{ }^{\circ} \mathrm{F}\right)$. From Equation [4], it was calculated that $310,739 \mathrm{lbm} / \mathrm{hr}$ of cooling water is needed.

Cooler E-103 is an electric air cooler that will be used to cool the nylon 6,6 product from $518^{\circ} \mathrm{F}$ to $140^{\circ} \mathrm{F}$. To do this, the Aspen Plus simulation estimates that $2.26 \mathrm{MM} \mathrm{Btu} / \mathrm{hr}$ will be required, or 662 kW of electricity. The outlet temperature of $140^{\circ} \mathrm{F}$ was chosen as the temperature at which the air cooler would shut off. The design group chose $140^{\circ} \mathrm{F}$ based on heuristics found in Turton, et al [19]. The nylon 6,6 will continue to cool down unaided until it reaches ambient temperature. Using Equation [4], with the heat capacity of air being $0.25 \mathrm{Btu} /\left(\mathrm{lb}^{\circ} \mathrm{F}\right)$ and an estimated approach temperature of $40^{\circ} \mathrm{F}$, [19] it was calculated that the flowrate of air will be roughly $226 \mathrm{M} \mathrm{lbm} / \mathrm{hr}$.

## Reactors:

The polycondensation reaction that generates nylon 6,6 is slightly endothermic and needs to be maintained at a constant temperature of $518^{\circ} \mathrm{F}$ to ensure maximum conversion. Therefore, both the batch and continuously stirred tank reactors will need to contain a heat jacket. For both reactors, the temperatures need to be maintained at temperatures in excess of the temperature of high pressure steam. Therefore, high pressure steam cannot be used to maintain the temperatures in these reactors. Electric heaters will work best for this process instead. The design team made the decision to use these high temperatures because they will result in conversions close to $100 \%$. As a result, only trace amounts of ADA and HMDA are found in the product and vent streams. This allows the process to conserve mass and eliminate wastes.

The feed for Reactor R-101 (Stream 5) is at a temperature of $410^{\circ} \mathrm{F}$ and a pressure of 117.6 psia . When it enters Reactor R-101, it will need to be heated to and maintained at $518^{\circ} \mathrm{F}$ for the polycondensation reaction to occur. From the energy balance that takes place in Aspen Plus, 726 M Btu/hr of energy will need to be transferred to successfully heat Stream 5 to $518^{\circ} \mathrm{F}$ and maintain this temperature throughout the time the reaction is taking place in the reactor. As stated above, an electric heater will be used to provide the $726 \mathrm{M} \mathrm{Btu} / \mathrm{hr}$ of energy required. Thus, 213 kW of electricity will be needed.

Reactor R-102 will also require a reactor jacket to maintain a constant temperature of $518{ }^{\circ} \mathrm{F}$. This temperature is required in order to maximize conversion for the CSTR. From the energy
balance in Aspen Plus, $106 \mathrm{M} \mathrm{Btu} / \mathrm{hr}$ of energy, or 31 kW , is required to heat the reactor and will also be provided by an electric heater.

## Pumps:

Only one pump is needed in this design to produce the optimum pressures for nylon 6,6 production. Pump P-101 is used to pressurize the mixed feed of ADA, HMDA, and water. Stream 3 enters Pump P-101 at a pressure of 14.7 psia , and is pumped to a pressure of 120 psia when it leaves the pump as Stream 4. This will require 5.6 kW of electricity.

## Extruders:

The extrusion unit is responsible for forming nylon 6,6 pellets from the nylon 6,6 product stream. The product stream is at $518^{\circ} \mathrm{F}$, and exits at atmospheric pressure, where it will be subsequently cooled by Air Cooler E-103. The extruder will require 55 kW of electricity to produce the nylon 6,6 pellets. It is labeled X-101.

A summary of the utility requirements for the two heat exchangers can be found below in Figure $\mathbf{1 4}$, and a summary of the utility requirements for the reactors, pump, and extruder can be found below in Figure 15.

| Heat Exchanger | Energy <br> Requirements <br> (Btu/hr) | Steam Flowrate <br> (lbm/hr) | Cooling Water <br> Flowrate <br> (lbm/hr) | Electricity <br> Requirements <br> $(\mathbf{k W})$ |
| :--- | :---: | :---: | :---: | :---: |

Figure 15: Reactors, Pump, and Extruder Utility Requirement Summary

The design team was also tasked with designing the process equipment for a $67 \%$ turndown case. While equipment sizing will stay the same, energy and utility requirements will be affected. The same equations and calculations are used for the turndown case, and energy requirements and flow rates are decreased by $33 \%$. Figures 16 and 17 summarize the $67 \%$ turndown utility requirements for heat exchangers and the reactors, pump, and extruder, respectively.

## Pumps:

A summary of the pump is given by Figure 19 below.

| Pump P-101 |  |  |  |
| :--- | :---: | :--- | :---: |
| $\Delta \mathrm{P}$ | 105.3 | $\mathrm{Q}\left(\mathrm{ft}^{3} / \mathrm{hr}\right)$ | 3339 |
| $\mathrm{P}_{\text {discharge }}$ (psia) | 120 | $\dot{\mathrm{~m}}(\mathrm{lbm} / \mathrm{hr})$ | 13,810 |
| $\mathrm{P}_{\text {Suction }}(\mathrm{psia})$ | 14.7 | $\eta_{\text {motor }}$ | 0.86 |
| $\mathrm{P}_{\text {Design }}(\mathrm{psia})$ | 170 | $\eta_{\text {Pump }}$ | 0.45 |
| $\rho_{\text {Fluid }}\left(\mathrm{lbm} / \mathrm{ft}^{3}\right)$ | 61.84 | Hydraulic Hp | 3.42 |
| $\rho_{\text {Water }}\left(\mathrm{lbm} / \mathrm{ft}^{3}\right)$ | 62.37 | Brake Hp | 7.51 |
| Specific Gravity | 0.992 | Purchased Hp | 8.73 |

Figure 19: Pump P-101 Summary Design Table

A sensitivity analysis was completed in Aspen Plus to determine the optimum pressure required for the process. Figure 20 shows that that the degree of polymerization maximizes around a design pressure of 155 psig . For this reason, we chose to use P-101 to increase the feed pressure to 155 psig , or 170 psia. The feed streams are entirely liquid, and therefore a pump was chosen over a compressor. The design team chose to use a centrifugal pump because of its versatility in flow capacity. The centrifugal pump allows for a greater range of flow rates than a positive displacement or reciprocating pump. This will allow us to be a lot more flexible in regards to any changes in flow rate required. Three options were considered for the centrifugal pump: a standard pump with axial flow, a turbine pump with mixed flow, and a propeller pump with axial flow. A standard centrifugal pump was chosen because it is the only centrifugal pump able to handle the 245 ft of pressure head required. The flow streams are also not abrasive or contain a high solid content [20].

Figure 20: Pressure Sensitivity analysis

The Aspen Plus simulation program was used to assist in pump design. Aspen calculated the pressure head, hydraulic horsepower, and brake horsepower based on the volumetric flowrate and pressure change in the pump. Aspen Plus estimated the pump efficiency of 0.45 based on the flow conditions and fluid in the process. Using the Aspen Plus estimated brake horsepower of 7.51, we were able to use Figure 21 to determine that the motor efficiency is approximately 0.86 . Dividing the brake horsepower by the motor efficiency results in a purchased horsepower of 8.73. Thus a 10 horsepower electric motor is required for pump P-101.

Figure 21: Centrifugal Pump Motor Efficiency [21]

The material of construction (MOC) for pump P-101 is carbon steel. Carbon steel is the least expensive and thus the most economic choice for material of construction. The Nylon salt feed stream is not corrosive to carbon steel, and carbon steel is capable of handling the pressures and temperatures that the pump will encounter. One spare pump will also be required and costed for in order to avoid a shutdown if there should be any maintenance requirements for the pump. The Pump Specification sheet is found on Page $\mathbf{3 5}$ of this report, and the costing summary for this piece of equipment can be found on Page 75.

## Heat Exchangers:

Three different heat exchangers were used for this process. E-101 is used to heat the nylon salt feed stream, E-102 is used to cool the combined water vent stream at the end of the process, and E-103 is used to cool the nylon 6,6 product. Heat exchangers E-101 and E-102 are basic countercurrent flow shell and tube heat exchangers. The design team chose this model because of its ease of design and heat transfer capabilities [21].

The shell and tube configuration allows us to minimize the heat transfer area required, while the countercurrent configurations allows for maximum heat transfer. For both E-101 and E-102, Carbon steel was chosen as the MOC for the shell because it is inexpensive and we do not have to worry about any corrosion in the shell due the nylon salt solution. Stainless steel was chosen as the tube material because water and steam have been found to be quite corrosive on carbon steel heat exchanger tubes [22]. Stainless steel is much more resistant to fouling caused by water, and should last much longer in the field [22]. Cooler E-103 is an air cooler connected with the nylon 6,6 extruder. Carbon steel was chosen as its MOC because air is not corrosive to carbon steel, and carbon steel is the most cost effective. Figure 22 is a design summary table for Heater E-101.

| Heater E-101 |  |  |  |
| :---: | :---: | :---: | :---: |
| Q (Btu/hr) | 2,340,000 | Feed m $(\mathrm{lbm} / \mathrm{hr})$ | 13,810 |
| Feed $\mathrm{T}_{\text {in }}\left({ }^{\circ} \mathrm{F}\right)$ | 140 | Steam m ${ }^{\text {( } \mathrm{lbm} / \mathrm{hr} \text { ) }}$ | 3,250 |
| Feed $\mathrm{T}_{\text {out }}\left({ }^{\circ} \mathrm{F}\right)$ | 410 | Steam v (gpm) | 300 |
| Steam $\mathrm{T}_{\text {in }}\left({ }^{\circ} \mathrm{F}\right)$ | 489 | $\mathrm{U}_{0}\left(\mathrm{Btu} / \mathrm{hr}-{ }^{\circ} \mathrm{F}-\mathrm{ft}^{2}\right)$ | 130 |
| Steam $\mathrm{T}_{\text {out }}\left({ }^{\circ} \mathrm{F}\right)$ | 489 | F | 1 |
| $\Delta \mathrm{T}_{\mathrm{lm}}$ | 181.7 | Number of shells | 1 |
| $\mathrm{P}_{\text {Design }}$ (psia) | 170 | A ( $\mathrm{ft}^{2}$ ) | 91.4 |

Figure 22: Heater E-101 Design Summary

The Aspen Plus simulation specifies that a heat duty of $2.34 \mathrm{MM} \mathrm{Btu} / \mathrm{hr}$ is required to heat the feed stream to the required temperature. This value was used in the preceding section to generate the mass flow rate of steam needed for the heat transfer. This value can be used with Equation [5] to estimate the size of the heater.

$$
\begin{equation*}
A=\frac{Q}{U_{0} F \Delta T_{l m}} \tag{5}
\end{equation*}
$$

Where: $\mathrm{A}=$ heat exchanger area, $\mathrm{ft}^{2}$
$\mathrm{Q}=$ heat duty, Btu/hr
$\mathrm{U}_{0}=$ overall heat transfer coefficient, $\mathrm{Btu} / \mathrm{hr}^{\circ}{ }^{\circ} \mathrm{F}-\mathrm{ft}^{2}$
$\mathrm{F}=$ correction factor to account for the departure from true countercurrent flow $\Delta \mathrm{T}_{\mathrm{lm}}=\log$ mean temperature difference.

The overall heat transfer coefficient, $\mathrm{U}_{0}$, has been estimated to be approximately $130\left(\mathrm{Btu} / \mathrm{hr}-{ }^{\circ} \mathrm{F}\right.$ $\mathrm{ft}^{2}$ ). The design team made this decision based on heuristics given in Turton, et al [19]. Correction factor F is approximately 1.0 because the high pressure steam used for heat transfer is condensing inside the heat exchanger. The log mean temperature difference can be found using Equation [6].

$$
\begin{equation*}
\Delta T_{l m}=\frac{\left(\text { Steam } T_{\text {in }}-\text { Feed } T_{\text {in }}\right)-\left(\text { Steam } T_{o u t}-\text { Steam } T_{o u t}\right)}{\ln \left[\frac{\left(\text { Steam } T_{\text {in }}-\text { Feed } T_{\text {in }}\right)}{\left(\text { Steam } T_{\text {out }}-\text { Steam } T_{o u t}\right)}\right]} \tag{6}
\end{equation*}
$$

The values for each temperature are located in Figure 22. Heater E-101 needs to have an area of $91 \mathrm{ft}^{2}$. This value will be used to estimate the capital and manufacturing costs found on Page 75. To avoid any shutdowns due to heater malfunction, we are requiring that a spare heater be purchased for this process. The design specification sheet for E-101 is found on Page 36.

Figure 23 is a design summary table for Cooler E-102.

| Cooler E-102 |  |  |  |
| :---: | :---: | :---: | :---: |
| Q (Btu/hr) | 4,080,000 | Feed m $(\mathrm{lbm} / \mathrm{hr})$ | 10,250 |
| Feed $\mathrm{T}_{\text {in }}\left({ }^{\circ} \mathrm{F}\right)$ | 363 | Water m ( $\mathrm{lbm} / \mathrm{hr}$ ) | 310,739 |
| Feed $\mathrm{T}_{\text {out }}\left({ }^{\circ} \mathrm{F}\right)$ | 100 | Water v (gpm) | 688 |
| Cooling Water $\mathrm{T}_{\text {in }}\left({ }^{\circ} \mathrm{F}\right)$ | 87 | $\mathrm{U}_{0}\left(\mathrm{Btu} / \mathrm{hr}-{ }^{\circ} \mathrm{F}-\mathrm{ft}^{2}\right)$ | 130 |
| Cooling Water $\mathrm{T}_{\text {out }}\left({ }^{\circ} \mathrm{F}\right)$ | 100 | F | 0.84 |
| $\Delta \mathrm{T}_{\mathrm{lm}}$ | 34.8 | Number of shells | 1 |
| $\mathrm{P}_{\text {Design }}$ (psia) | 64.7 | A ( $\mathrm{ft}^{2}$ ) | 1074 |

Figure 23: E-102 Design Summary

According to data obtained from the Aspen Plus simulation, 4.08 MM Btu/hr need to be removed from the combined vent stream in order to properly cool the wastewater to a temperature where it can be properly treated and disposed of. This is done by heating up cooling water to near $100{ }^{\circ} \mathrm{F}$. Equation [5] can once again be used to estimate the heat transfer area required for E-102, where Equation [6] is once again used to determine the log mean temperature difference. The calculations used to determine the correction factor can be found in the appendix. However, it was found that the inlet and outlet temperatures of the cooling water and vent stream are great enough that the correction factor is approximately 1 . The required estimated area for heat transfer is $1074 \mathrm{ft}^{2}$ for $\mathrm{E}-102$. A spare cooler is required for design.

The design specification sheet for E-102 is found on Page 37, and a costing summary is found on Page 76.

Figure 24 is a design summary table for Air Cooler E-103.

| Air Cooler E-103 |  |  |  |
| :--- | :---: | :--- | :---: |
| Q (Btu/hr) | $2,260,000$ | Feed $\dot{\mathrm{m}}(\mathrm{lbm} / \mathrm{hr})$ | 3560 |
| Feed $\mathrm{T}_{\text {in }}\left({ }^{\circ} \mathrm{F}\right)$ | 518 | Air $\dot{\mathrm{m}}(\mathrm{lbm} / \mathrm{hr})$ | 226,000 |
| Feed $\mathrm{T}_{\text {out }}\left({ }^{\circ} \mathrm{F}\right)$ | 140 | Air v $(\mathrm{gpm})$ | 941 |
| Cooling air $\mathrm{T}_{\text {in }}\left({ }^{\circ} \mathrm{F}\right)$ | 70 | $\mathrm{U}_{0}\left(\mathrm{Btu} / \mathrm{hr}-{ }^{\circ} \mathrm{F}-\mathrm{ft}^{2}\right)$ | 90 |
| Cooling air $\mathrm{T}_{\text {out }}\left({ }^{\circ} \mathrm{F}\right)$ | 110 | F | 1 |
| $\Delta \mathrm{~T}_{\operatorname{lm}}$ | 155 | $\mathrm{~A}\left(\mathrm{ft}^{2}\right)$ | 162 |
| $\mathrm{P}_{\text {Design }}(\mathrm{psia})$ | 64.7 |  |  |

Figure 24: E-103 Design Summary

The design team chose to use an air cooler because the nylon 6,6 will be in pellet form after exiting the extruder. E-103 relies on electricity to power the fan. According to the Aspen Plus simulation, $2.26 \mathrm{MM} \mathrm{Btu} / \mathrm{hr}$, or 662 kW of electricity, is required to cool the nylon 6,6 product stream. For this preliminary design, the design team estimated the ambient air temperature to $70^{\circ} \mathrm{F}$, with the understanding that this can change on a day to day basis unless the air cooler is located indoors. The air outlet temperature and overall heat transfer coefficient were chosen based on design heuristics found in Turton, et al [19]. These values are $140^{\circ} \mathrm{F}$ and $90 \mathrm{Btu} / \mathrm{hr}-{ }^{\circ} \mathrm{F}$ $\mathrm{ft}^{2}$, respectively. The correction factor was estimated to be approximately 1 since air cooling is occurring in place of a conventional countercurrent heat exchanger. Equation [5] is once again
used to calculate the heat transfer area of the cooler, with Equation [6] used to calculate the log mean temperature difference.

The design specification sheet for E-103 is found on Page 38, and a costing summary is found on Page 76.

## Reactors:

Reactors R-101 and R-102 are used to convert the ADA, HMDA, and water feed to nylon 6,6 . $\mathrm{R}-101$ is a batch reactor that converts the reactants to nylon salt at a temperature of $518{ }^{\circ} \mathrm{F}$ and a pressure of 121 psia. R-102 then converts the nylon salt solution to nylon 6,6 by reducing the pressure to 8.33 psia , while maintaining the temperature of $518^{\circ} \mathrm{F}$. Carbon steel was chosen as the MOC due to its inexpensiveness and the lack of highly corrosive chemicals in the process. The reasons for using a batch reactor followed by a CSTR were explained in the previous Process Description section. Figure 25 below is a design summary table for Reactor R-101.

| Batch Reactor R-101 |  |  |  |
| :--- | :---: | :--- | :---: |
| $\mathrm{T}\left({ }^{\circ} \mathrm{F}\right)$ | 518 | $\mathrm{~N}_{\mathrm{A} 0}(\mathrm{lbmol})$ | 45.4 |
| $\mathrm{P}_{\text {Design }}(\mathrm{psia})$ | 17 | $\mathrm{~N}_{\mathrm{A}}(\mathrm{lbmol})$ | 0.012 |
| $\dot{\mathrm{~m}}_{\text {in }}(\mathrm{lbm} / \mathrm{hr})$ | 13,810 | Conversion | 0.9997 |
| Vent $\dot{\mathrm{m}}_{\text {out }}(\mathrm{lbm} / \mathrm{hr})$ | 3,431 | $\mathrm{Q}(\mathrm{Btu} / \mathrm{hr})$ | 726,000 |
| Product <br> $(\mathrm{lbm} / \mathrm{hr})$ |  |  |  |
| $\rho_{\text {out }}\left(\mathrm{lbm} / \mathrm{ft}^{3}\right)$ | 10,379 | Electricity <br> Requirement $(\mathrm{kW})$ | 213 |
| $(\mathrm{hr})$ | 52.66 | $\mathrm{~V}\left(\mathrm{ft}^{3}\right)$ | 437.1 |

Figure 25: R-101 Design Summary
Reactor R-101 is a batch reactor that will be used to convert the feed into aqueous nylon salt. Because the reaction is slightly endothermic, this reactor will require a heated jacket in order to maintain the temperature of $518^{\circ} \mathrm{F}$. Polymerization has been shown to increase with temperature up to the point of thermal degradation. The design group chose $518^{\circ} \mathrm{F}$ as the design temperature because it is the highest temperature observed in the literature that does not show signs of thermal degradation [23, 24]. Because this temperature is higher than that of high pressure steam, an electric heater will be needed to provide the heat. The design group chose to use a non-agitated heating jacket because we do not foresee any need for an agitated one. The energy
balance was developed in the Aspen Plus simulation, and $726 \mathrm{M} \mathrm{Btu} / \mathrm{hr}$ is needed to raise the feed to $518^{\circ} \mathrm{F}$, and be maintained throughout the reaction. This corresponds to an electricity requirement of 142 kW . Equation [7] is the batch reactor design equation, which is used to determine the volume of the reactor vessel needed for this reaction.

$$
\begin{equation*}
N_{A 0} \frac{d X}{d t}=-r_{A} V \tag{7}
\end{equation*}
$$

Where: $\mathrm{N}_{\mathrm{A} 0}=$ initial amount of adipic acid in the reactor, lbmol
$\mathrm{X}=$ conversion
$\mathrm{r}_{\mathrm{A}}=$ reaction rate, $\mathrm{lbmol} / \mathrm{ft}^{3}-\mathrm{hr}$
$\mathrm{V}=$ reactor volume, $\mathrm{ft}^{3}$
The reactor volume was calculated by using the batch reactor sizing techniques found in Turton, et al. The total reactor volume is found by Equation [8].

$$
\begin{equation*}
V=\frac{\dot{m}}{\rho}\left(\frac{5}{3}\right) \tag{8}
\end{equation*}
$$

Where: $\dot{\mathrm{m}}=$ feed flow rate, $\mathrm{lbm} / \mathrm{hr}$,
$\rho=$ density, lbm/ft
The $5 / 3$ term is a multiplication value to account for the assumption that the reactor is $60 \%$ full while in operation. This value was found in Turton, et al. Using Equation [8] and the values for $\dot{m}$ and $\rho$ in Figure 25, the estimated required volume for the Reactor R-101 can be calculated to be $437.1 \mathrm{ft}^{3}$. Equation [9] can be used to determine the reaction conversion in the batch reactor.

$$
\begin{equation*}
X=1=\frac{N_{A}}{N_{A 0}} \tag{9}
\end{equation*}
$$

$\mathrm{N}_{\mathrm{A} 0}$, the initial number of moles of adipic acid, is equal to 45.37 lbmol . According to the Aspen Plus simulation, the final number of moles of adipic acid in the stream, $\mathrm{N}_{\mathrm{A}}$, is 0.0123 lbmol . Thus the reaction conversion for Reactor R-101 is 0.9997 .

Through a sensitivity analysis, it was determined that the optimum residence time for the reaction is approximately 1 hour. Leaving the reactants in the reactor for this amount of time results in the highest possible conversion of nylon salt. Figure 26 is a graph of the molar concentrations vs time, showing that 1 hour is the optimum residence time for this reactor.

Figure 26: Molar Concentrations vs Time

Because the residence time is one hour, there will be at least one hour of dead time for the reactor. In order to maintain a smooth process, $\mathrm{R}-101$ represents two identical reactors in parallel. While R-101 A is producing nylon salt, R-101 B will be filling up with reactants, and vice versa. This will allow for another batch of nylon salt to be produced while R-101 A is experiencing dead time. Thus the process of producing nylon 6,6 will be sped up, and there will not be a buildup of feed or reactants upstream. The design specification sheet for R-101 is found on Page 39, and a costing summary is found on Page 75. Figure 27 is a design summary table for Reactor R-102.

| R-102 |  |  |  |
| :--- | :---: | :--- | :---: |
| $\mathrm{T}\left({ }^{\circ} \mathrm{F}\right)$ | 518 | $\mathrm{v}_{0}\left(\mathrm{ft}^{3} / \mathrm{hr}\right)$ | 192.5 |
| $\mathrm{P}_{\text {Design }}(\mathrm{psia})$ | 58.33 | $(\mathrm{~min})$ | 3 |
| $\dot{\mathrm{~m}}_{\text {in }}(\mathrm{lb} / \mathrm{hr})$ | 10,379 | Conversion | 1 |
| Vent $\dot{\mathrm{m}}_{\text {in }}(\mathrm{lb} / \mathrm{hr})$ | 129 | $\mathrm{Q}(\mathrm{Btu} / \mathrm{hr})$ | 106,000 |
| Product $\dot{\mathrm{m}}_{\text {in }}(\mathrm{lb} / \mathrm{hr})$ | 10,250 | Electricity Requirement $(\mathrm{kW})$ | 31 |
| $\mathrm{~F}_{\mathrm{A} 0}(\mathrm{lbmol} / \mathrm{hr})$ | 45.3 | $\mathrm{~V}\left(\mathrm{ft}^{3}\right)$ | 548.6 |
| $\rho\left(\mathrm{lb} / \mathrm{ft}^{3}\right)$ | 52.66 |  |  |

Figure 27: R-102 Design Summary

Reactor R-102 is a continuously stirred tank reactor (CSTR) that is used to convert the nylon salt stream from R-101 into nylon 6,6. The reactor does this by lowering the pressure to 8.33 psia and venting out what water remains in the process. The pressure was chosen as it was the ideal pressure found in the literature. This results in the nylon molecules attaching to each other and forming nylon 6,6 . Like R-101, R-102 will require a heated jacket to maintain a constant temperature of $518{ }^{\circ} \mathrm{F}$. The temperature on R-102 was selected for the same reasons as R-101. An electric heater and a not-agitating jacket were chosen for similar reasons as those for R-101. According to the Aspen Plus simulation, $71 \mathrm{M} \mathrm{Btu} / \mathrm{hr}$ are required to maintain the reactor temperature at a constant $518^{\circ} \mathrm{F}$, corresponding to an electricity requirement of 21 kW .

The CSTR design equation is shown in Equation 10 below.

$$
\begin{equation*}
V=\frac{F_{A 0} X}{-r_{A}} \tag{10}
\end{equation*}
$$

Where: $\mathrm{V}=$ volume, $\mathrm{ft}^{3}$,
$\mathrm{F}_{\mathrm{A} 0}=$ flowrate of nylon salt feed, $\mathrm{lbmol} / \mathrm{hr}$
$\mathrm{X}=$ conversion from nylon salt to nylon 6,6
$\mathrm{r}_{\mathrm{A}}=$ reaction rate, $\mathrm{lbmol} / \mathrm{ft}^{3}-\mathrm{hr}$

The conversion is assumed to be 1 because all of the nylon salt (excluding water) is being converted to nylon 6,6 . The reaction rate is explained fully in the Process Description section. The value for $\mathrm{F}_{\mathrm{A} 0}$ is found in Figure 27, and is equal to $45.3 \mathrm{lbmol} / \mathrm{hr}$.

The reactor volume was calculated by using Equation 11 below:

$$
\begin{equation*}
V=\tau v_{o} \tag{11}
\end{equation*}
$$

Where: $\tau=$ residence time (minutes)
$\mathrm{v}_{0}=$ initial volumetric flow rate ( $192.5 \mathrm{ft}^{3} / \mathrm{hr}$ )

The residence time for $\mathrm{R}-102$ was determined to be 0.05 hours, or 3 minutes. A sensitivity analysis for the degree of polymerization was completed to determine this value. Figure 28 shows the sensitivity analysis. The residence time chosen is not quite at the peak of the graph. This was done because the reactor volume drastically alters the capital costs of the reactor. The design group chose a residence time of 0.05 hours because this value results in the lowest capital cost while remaining a marginal difference in the optimum degree of polymerization.
From Equation 11, the volume of R-102 is $577.5 \mathrm{ft}^{3}$.

Figure 28: R-102 Residence Time Sensitivity Analysis
$\mathrm{R}-102$ will contain a spare reactor vessel in order to avoid complete shutdown due to any equipment malfunctions. The design specification sheet for R-102 is found on Page 40, and a costing summary is found on Page 75.

## Process Vessels:

Figure 29 is a design summary for Process Vessel V-101.

| V-101 |  |  |  |
| :--- | :---: | :--- | :---: |
| $\mathrm{T}\left({ }^{\circ} \mathrm{F}\right)$ | 518 | $\mathrm{~V}_{0}\left(\mathrm{ft}^{3} / \mathrm{hr}\right)$ | 192.5 |
| $\mathrm{P}_{\text {Design }}(\mathrm{psia})$ | 171 | $\mathrm{~V}\left(\mathrm{ft}^{3}\right)$ | 64 |
| $\dot{\mathrm{~m}}(\mathrm{lbm} / \mathrm{hr})$ | 10,379 | $\mathrm{~L} / \mathrm{D}$ | 3 |
| $\rho\left(\mathrm{lbm} / \mathrm{ft}^{3}\right)$ | 52.66 | $\mathrm{~L}(\mathrm{ft})$ | 9 |
| Holdup time (min) | 10 | $\mathrm{D}(\mathrm{ft})$ | 3 |
| $\mathrm{~L} / \mathrm{D}$ | 3 |  |  |

Figure 29: V-101 Design Summary

The design team made the decision to add a process vessel after Reactor R-101. Vessel V-101 will act as a holding tank for the nylon salt solution before it continues on in the process. Vessel V-101 will provide time to identify any issues with the nylon salt solution, and also provide a way to drain the process should the reaction taking place in R-101 fail for any reason, or produce
an impure product. Placing this vessel before R-102 will save the company utility costs associated with R-102 should the first reaction fail.

Following the design heuristics in Turton, et al [19], the ideal length to volume ratio is 3, the average holdup time should be approximately 10 minutes, and the vessel should be assumed to be $50 \%$ full at all times. Therefore, Equation 12 can be used to determine the vessel volume.

$$
\begin{equation*}
V=2 \dot{m} t_{\text {holdup }} \tag{12}
\end{equation*}
$$

Here, $\dot{\mathrm{m}}$ is the volumetric flow rate into $\mathrm{V}-101$, and is equal to $192.5 \mathrm{ft}^{3} / \mathrm{hr}$. Thus, the volume required for V-101 is equal to $64 \mathrm{ft}^{3}$. Assuming that V-101 is a horizontal cylinder and using an $\mathrm{L} / \mathrm{D}$ of 3 , vessel length is calculated to be 9 ft and the vessel diameter to be 3 ft .

Vessel V-101 will be made of carbon steel due to its low cost. The design specification sheet for V-101 is found on Page 41, and a costing summary is found on Page 75.

## Extruder:

An extruder, $\mathrm{X}-101$, is required near the end of the process to produce the nylon 6,6 pellets that will be sold. The design team investigated different extruders, and finally decided on the plastic extruder machine manufactured by Longshi (Dongguan) Machinery Plastic Company, Ltd located in Shenzhen, China [25]. This particular extrusion unit is made of nitrided steel and has dimensions of $11 \mathrm{ft} \times 5.9 \mathrm{ft} \times 5.2 \mathrm{ft}$. It is computerized and thus produces the nylon 6,6 pellets automatically. The model number is NR-II-46-001. Two extruder units will be purchased so that a spare will be present on site. The design specification sheet for $\mathrm{X}-101$ is found on Page 42, and a costing summary is found on Page 75.

## Equipment Specification Sheets: Table of Contents

The following eight pages consist of equipment specification sheets for the process equipment used in this design. Figure $\mathbf{3 0}$ below is a table of contents for the equipment specification sheets.

| Equipment Specification Sheet | Location |

## Product Receiver Vessel

## Capital Cost Summary

The cost for each piece of equipment was estimated by using the module costing technique in Turton, et al [19]. In this approach, costs are first calculated for base conditions and then adjusted based on the equipment type, system pressure, and materials of construction in a specific design. Base conditions are assumed to be equipment made of carbon steel and operating at near-ambient pressures. The bare module cost for a given piece of equipment can be calculated by using Equation 13, shown below.

$$
\begin{equation*}
C_{B M}=C_{p}^{o}\left[B_{1}+B_{2} F_{p} F_{M}\right] \tag{13}
\end{equation*}
$$

Where: $\mathrm{C}_{\mathrm{BM}}=$ bare module equipment cost, $\$$
$\mathrm{C}_{\mathrm{p}}{ }^{\mathrm{o}}=$ purchased cost in base conditions, $\$$
$B_{1}=$ equipment type factor
$\mathrm{B}_{2}=$ equipment type factor
$\mathrm{F}_{\mathrm{p}}=$ pressure factor
$\mathrm{F}_{\mathrm{M}}=$ material of construction factor

For heat exchangers, $\mathrm{F}_{\mathrm{p}}$ is calculated as shown below in Equation 14.

$$
\begin{equation*}
\log _{10} F_{p}=C_{1}+C_{2} \log _{10} P+C_{3}\left(\log _{10} P\right)^{2} \tag{14}
\end{equation*}
$$

Where: $\mathrm{C}_{\mathrm{i}}=$ pressure factor
$\mathrm{P}=$ pressure, barg

For process vessels, $\mathrm{F}_{\mathrm{p}}$ can be calculated using Equation 15. Unless otherwise specified, CA is assumed to be 0.00315 m and $\mathrm{t}_{\text {min }}$ is assumed to be 0.0063 m .

$$
\begin{equation*}
F_{p}=\frac{\frac{(P+1) D}{(2)(944)(0.9)-1.2(P+1)}+C A}{t_{\min }} \tag{15}
\end{equation*}
$$

Where: $\mathrm{P}=$ pressure, barg
$\mathrm{D}=$ diameter, m
$\mathrm{CA}=$ corrosion allowance, m
$\mathrm{t}_{\text {min }}=$ minimum allowable vessel thickness, m

The costs calculated using the above equations can then be adjusted to account for inflation by using the Chemical Engineering Plant Cost Index (CEPCI) by using Equation 16.

$$
\begin{equation*}
C_{2}=C_{1}\left(\frac{I_{2}}{I_{1}}\right) \tag{16}
\end{equation*}
$$

Where: $\mathrm{C}_{\mathrm{i}}=$ purchased cost, $\$$
$\mathrm{I}_{\mathrm{i}}=$ cost index

The purchased costs and bare module costs for each piece of equipment for both the Batch/CSTR and PFR/CSTR options are shown in Figures 31 and 32, respectively.

| Batch/CSTR Equipment Costs |  |  | PFR/CSTR Equipment Costs |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathrm{C}_{\mathrm{p}, 2016}$ | $\mathrm{C}_{\text {BM,2016 }}$ |  | $\mathbf{C}_{\mathrm{p}, 2016}$ | $\mathrm{C}_{\text {BM,2016 }}$ |
| P-101 | \$ 6,200 | \$ 16,000 | P-101 | \$ 6,200 | \$ 16,000 |
| E-101 | \$ 38,000 | \$ 96,000 | E-101 | \$ 38,000 | \$ 96,000 |
| R-101 | \$ 66,000 | \$ 265,000 | R-101 | \$ 75,000 | \$ 290,000 |
| V-101 | \$ 8,800 | \$ 23,500 | V-101 | \$ 8,800 | \$ 23,000 |
| R-102 | \$ 76,500 | \$ 306,000 | R-102 | \$ 77,000 | \$ 310,000 |
| E-102 | \$ 54,000 | \$ 138,000 | E-102 | \$ 50,000 | \$ 130,000 |
| E-103 | \$ 32,500 | \$ 106,000 | E-103 | \$ 35,000 | \$ 115,000 |

Figure 31: Batch/CSTR Capital Costs
Figure 32: PFR/CSTR Capital Costs

Because there were no available costing correlations for an extruder, the group requested a quote for an industrial extruder and pelletizer. An average price of $\$ 26,500$ [25] was used for calculations in this project.

Once the bare module cost has been determined, the total module cost can be calculated. This cost accounts for making small changes to an existing facility by adding contingency costs and fees to the bare module cost. For this project, the grassroots cost was also calculated. The grassroots cost includes costs for site development and auxiliary buildings, which are assumed to
be $50 \%$ of the total bare module cost. The total module cost is calculated by using Equation 17, and the calculation for the grassroots cost is shown in Equation 18.

$$
\begin{gather*}
C_{T M}=\sum_{i=1}^{n} C_{T M, i}=1.18 \sum_{i=1}^{n} C_{B M, i}  \tag{17}\\
C_{G R}=C_{T M}+0.50 \sum_{i=1}^{n} C_{B M, i}^{o} \tag{18}
\end{gather*}
$$

Working capital was approximated as $15 \%$ of the fixed capital costs, according to Turton et al [19]. The total capital investment can be calculated using Equation 19, shown below.

$$
\begin{equation*}
\text { Total Capital Investment }=\text { Fixed Capital }+ \text { Working Capital } \tag{19}
\end{equation*}
$$

Figure 33 shows a summary of all capital costs.

| Capital Costs |  |  |  |
| :--- | :---: | :--- | :---: |
|  | Batch/CSTR |  | PFR/CSTR |
| Fixed Capital (Grassroots) | $\$$ | $3,400,000$ | $\$$ |
| Working Capital | $\$$ | $510,000,000$ |  |
| Total Capital Investment | $\$$ | $4,025,000$ | $\$$ |

Figure 33: Summary of Capital Costs

## Safety, Health, and Environmental Considerations:

Throughout the development of this process plant, safety was kept at the forefront of all decisions. The first step to ensuring each step of the process was as safe as possible was an initial hazard analysis on the raw materials being used for this process. Figure 34 below displays an initial raw material hazard analysis.

| Material Properties | Hazard |
| :---: | :--- |
| Health | Nylon 6,6 |
| Adipic acid | Fine particulates may lead to eye or lung irritation upon exposure. In addition, <br> thermal decomposition may lead to the release of toxic or irritating vapors. |
| HMDA | Skin and eye irritant; hazardous in case of ingestion and inhalation. Repeat <br> exposure can cause organ damage. |
| Flammability | Substance is toxic to blood, kidneys, lungs, and liver. Very hazardous in case of <br> skin contact, eye contact, and inhalation. Inhalation of dust can lead to irritation <br> of gastrointestinal and respiratory tracts. |
| Adipic acid | Slightly flammable to flammable at high temperatures |
| HMDA | Slightly flammable to flammable at high temperatures |

Figure 34: Hazard Identification Summary [26-28]

Both adipic acid and HMDA have been found to be slightly flammable at elevated temperatures. Therefore, research was done into the probability of the raw materials catching fire, as well as any release limits set by the EPA. This research led to the conclusion that so long as the raw materials were not exposed to excessively high temperatures or open flame, the probability of fire was very low. In order to further mitigate flammability risks, the raw materials used were diluted with water so as to reduce the potential for combustion. Figures 35 and 36 below display the results of this flammability analysis.

|  | OSHA (PSM) | EPA (RMP) |  |  |
| :--- | ---: | ---: | ---: | :---: |
| Component | PEL (ppm) | Threshold Level (lbs) | Known Hazards |  |
| Water | N/A | N/A | N/A |  |
| Nylon 6,6 | N/A | N/A | N/A |  |
| Adipic acid | N/A | N/A | Flammable, Health Hazard |  |
| HMDA | N/A | N/A | Flammable, Health Hazard |  |

| Adipic acid | 2 | 1 | 0 | N/A |  |
| HMDA | 3 | 2 | 0 | N/A |  |

Figure 36: NFPA and Flammability Analysis

In order to avoid the release of any raw materials or product to the environment, all vent streams were set through wastewater treatment before being released. This necessary step ensures that any water released from this plant will not pose a negative impact to the environment or the surrounding Calvert City area.

After investigating the hazards associated with the raw materials themselves, an investigation into process hazards was also performed. This analysis used the identified hazards and determined ways to mitigate these hazards using inherently safe principles of design. These actions were turned into designed components of this process. Figure 37 below displays the results of this inherent safety analysis.

| Hazard | Inherent Safety Concept | Action |
| :--- | :--- | :--- |
| Nylon 6,6 Health <br> Hazard | Minimization | Send newly-produced pellets directly to <br> packaging to avoid development of irritating <br> dust or degradation |
| ADA Health Hazard | Moderation | Raw material diluted with water to reduce <br> irritation hazard |
| HMDA Health <br> Hazard | Moderation | Raw material diluted with water to reduce <br> irritation hazard |
| ADA Flammability <br> Hazard | Moderation | Raw material diluted with water to reduce <br> flammability |
| HMDA Flammability <br> Hazard | Moderation | Raw material diluted with water to reduce <br> flammability |
| High-Temperature <br> Heating Fluid <br> Thermal Hazard | Substitution | Use electric heaters in place of other <br> dangerous heating fluids |

Figure 37: Inherent Safety Analysis

Additional measures were put in place in order to enhance the safety of the process design. For instance, in choosing reactors for this process, the choice was made to use multiple reactors with lower volume as opposed to a larger single reactor. This aided in creating a more inherently safe design, as a lower volume of material would be reacting at once. In the event of an incident, less material will be released, thus causing less damage or harm to workers.

When designing heated jackets for the reactors themselves, the decision was made to use electric heaters as opposed to utilizing a high-heat capacity heating media. This allowed for high levels of heating without the danger that accompanies such a media, thus eliminating another potential hazard.

For the design of shell-and-tube heat exchangers E-101 and E-102, stainless steel was chosen as the material of construction in order to avoid corrosion and the potential combination of water/steam with process material. If the process materials were to come in contact with the high pressure steam of E-101, the feed would become contaminated, and could potentially lead to thermal degradation. This breach would cause a safety problem, as well as lead to poorquality nylon product.

All process equipment was designed for 50 psi above operating pressure so as to provide a safety cushion in the event of elevated temperatures or pressures inside the equipment. In addition, all vent streams were cooled to $100^{\circ} \mathrm{F}$ before being sent to wastewater treatment in order to avoid the release of high-energy heated water or steam. In the event of an accidental release of the vent stream, the lowered temperature will prevent potential burns or injury that could result from a high-energy heated water stream. In a similar manner, the freshly extruded nylon pellets at the end of the process are immediately cooled in order to ensure they are safe to handle.

A process vessel was added in between R-101 and R-102 in order to provide greater control over the process and to serve as a safety measure. This process could have been designed to have aqueous nylon flow directly from R-101 and R-102, but this choice could have posed problems in the event of any disruption to the process. The current design's inclusion of vessel V-101 allows operators to drain $\mathrm{R}-101$ and stop the process if any part of the process is malfunctioning. In the case of an incident, the addition of a holding tank in between reactors helps to reduce the consequences of a malfunction.

Safety also played a role in the ultimate decision of reactor scheme. As previously mentioned, PFR/CSTR and CSTR/CSTR reactor schemes were also investigated in addition to the final Batch/CSTR scheme. The design group ultimately decided on the Batch/CSTR scheme because of its simplicity and safety. Batch reactors are inherently simpler than plug-flow reactors, and thus the group decided that ensuring the safety of such a reactor would be easier. The Batch/CSTR scheme also yielded a more profitable process, but only marginally more so than
the PFR/CSTR scheme. Therefore, the added simplicity and safety of the Batch/CSTR process was the deciding factor in choosing a final design.

As previously mentioned, safety was considered in all steps of the process design of this process. In addition to the previously mentioned analyses and considerations, a HAZOP analysis was performed to investigate the future steps needed to ensure the safety and hazard mitigation of the process in future design steps. The results of this analysis can be found on the following pages.
Figure 37 below details the various parts of the HAZOP analysis and where to find them on subsequent pages.

| Equipment Label | Equipment Name | HAZOP Table <br> Location |

## Manufacturing Costs

In order to more accurately assess which process was the most economically attractive, the manufacturing costs were estimated to account for any costs associated with day-to-day operation of the facility. Manufacturing costs for this project include operating labor cost, utilities, and water treatment.

To calculate the cost of operating labor, the number of non-particulate processing steps, $\mathrm{N}_{\mathrm{np}}$, must be determined.

$$
\begin{equation*}
N_{n p}=\sum \text { Equipment } \tag{20}
\end{equation*}
$$

The number of operators required per shift can then be calculated using Equation 21, shown below.

$$
\begin{equation*}
N_{O L}=\left(6.29+31.7 P^{2}+0.23 N_{n p}\right)^{0.5} \tag{21}
\end{equation*}
$$

Where: $\mathrm{N}_{\mathrm{OL}}=$ number of operators per shift
$\mathrm{P}=$ number of processing steps involving particulate solids
$\mathrm{N}_{\mathrm{np}}=$ nonparticulate processing steps
The total number of operators that will need to be hired to cover all shifts can be calculated by using Equation 22 and rounding up to the nearest integer.

$$
\begin{equation*}
N_{O L, t o t a l}=4.5\left(N_{O L}\right) \tag{22}
\end{equation*}
$$

The total operating labor cost can then be calculated by multiplying by salary. The average salary for chemical plant operators is approximately $\$ 59,580$ [19]. Figure 39 shows the results of all calculations related to the cost of operating labor.

| Operating Labor Cost |  |  |
| :--- | :---: | :---: |
| Pieces of Equipment | 8 |  |
| Operators Required per Shift | 2.85 |  |
| Total Operators Required | 13 |  |
| Cost of Labor $(\$ / \mathrm{yr})$ | $\$$ |  |
| CoL $(\$ / \mathrm{yr})$ | $\$ 775,580$ |  |

Figure 39: Operating Labor Costs

The cost for raw materials will be the same for both process options. The raw material cost was calculated using the prices shown in Figure 40.

| Raw Material Costs |  |  |  |  |
| :--- | :--- | :--- | :--- | :---: |
|  | Unit Price (\$/lbm) | Annual Price (\$/yr) |  |  |
| Adipic Acid | $\$$ | 0.68 | $\$$ | $37,00,000$ |
| Hexamethylenediamine | $\$$ | 1.14 | $\$$ | $50,000,000$ |

Figure 40: Raw Material Costs

Utility costs include the costs for cooling water, steam, or electricity requirements. Once the appropriate values for these requirements have been calculated, they can be multiplied by the unit price in order to yield the utility cost for a given piece of equipment. Summaries of the utility costs for the Batch/CSTR and PFR/CSTR options are given in Figures 41 and 42. The process vessel, V -101, does not use utilities, which is shown by ' X ' in the figures.

| Batch/CSTR Utility Costs |  |  |
| :--- | :--- | :---: |
| P-101 | $\$$ | 740 |
| E-101 | $\$$ | 128,000 |
| R-101 | $\$$ | 117,000 |
| V-101 |  |  |
| R-102 | $\$$ | 17,000 |
| E-102 | $\$$ | 900,000 |
| X-101 | $\$$ | 32,000 |
| E-103 | $\$$ | 385,000 |

Figure 41: Batch/CSTR Process Utility Costs

| PFR/CSTR Utility Costs |  |  |
| :--- | :--- | ---: |
| P-101 | $\$$ | 745 |
| E-101 | $\$$ | 128,000 |
| R-101 | $\$$ | $1,200,000$ |
| V-101 |  |  |
| R-102 | $\$$ | 17,000 |
| E-102 | $\$$ | 960,000 |
| X-101 | $\$$ | 32,000 |
| E-103 | $\$$ | 386,000 |

Figure 42: PFR/CSTR Process Utility Costs

This process includes a wastewater stream that must be treated before disposal. Similar to utility costs, the cost of this treatment is calculated by determining the amount of water to be treated and multiplying by the unit cost. Water treatment costs for the Batch/CSTR and PFR/CSTR options are shown in Figures 43 and 44.

| Batch/CSTR Water Treatment Costs |  |  |
| :--- | :--- | ---: |
| Water Removed $\left(\mathrm{ft}^{3}\right)$ | 485,000 |  |
| Water Treatment Cost $\left(\$ / 1000 \mathrm{ft}^{3}\right)$ | $\$$ | 1.17 |
| C WT $(\$ / \mathrm{yr})$ | $\$$ | 567 |

Figure 43: Batch/CSTR Process Water Treatment Costs

| PFR/CSTR Water Treatment Costs |  |  |
| :--- | :---: | :---: |
| Water Removed $\left(\mathrm{ft}^{3}\right)$ | 480,000 |  |
| Water Treatment Cost $\left(\$ / 1000 \mathrm{ft}^{3}\right)$ | $\$$ | 1.17 |
| $\mathrm{C}_{\mathrm{WT}}(\$ / \mathrm{yr})$ | $\$$ | 562 |

Figure 44: PFR/CSTR Process Water Treatment Cost

## Economic Analysis

For this project, the hurdle rate was assumed to be $15 \%$, and the effective tax rate was assumed to be $40 \%$ [19]. The project was evaluated over 10 years using a 10 years MACRS depreciation. To avoid incurring the entire fixed capital cost in the first year of the project life, the cost was split evenly between Year 1 (2018) and Year 2 (2019).

Important capital and manufacturing costs were discussed in previous sections for both the Batch/CSTR and PFR/CSTR processes. The costs for each process at both $100 \%$ and $67 \%$ capacity are shown in Figures 45-48.

| Batch/CSTR Cost Summary $\mathbf{- 1 0 0 \%}$ |  |  |
| :--- | :--- | ---: |
| Total Capital Investment | $\$$ | $4,025,000$ |
| Operating Labor Cost | $\$$ | 775,000 |
| Raw Materials | $\$$ | $87,000,000$ |
| Utility Cost | $\$$ | $1,600,000$ |
| Water Treatment | $\$$ | 570 |

Figure 45: Full Capacity Batch/CSTR Annual Cost Summary

| Operating Labor Cost | $\$$ | 775,000 |
| Raw Materials | $\$$ | $87,000,000$ |
| Utility Cost | $\$$ | $2,600,000$ |
| Wastewater Treatment | $\$$ | 570 |

Figure 47: Full Capacity PFR/CSTR Annual Cost Summary

| PFR/CSTR Cost Summary -67\% |  |  |
| :--- | :--- | ---: |
| Total Capital Investment | $\$$ | $4,600,000$ |
| Operating Labor Cost | $\$$ | 775,000 |
| Raw Materials | $\$$ | $58,000,000$ |
| Utility Cost | $\$$ | $1,700,000$ |
| Wastewater Treatment | $\$$ | 380 |

Figure 48: 67\% Capacity PFR/CSTR Annual Cost Summary

The annual production cost, which includes expenses related to the manufacturing of nylon 6,6, was calculated on an annual basis by summing the the costs of operating labor, raw materials, utilities, and wastewater treatment. That total was then divided by the total amount of nylon 6,6 produced per year to give the unit production cost, in $\$ 1.05 / \mathrm{lbm}$. The annual and unit production costs are shown below in Figure 49.

| Production Cost |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Batch/CSTR |  | PFR/CSTR |  |
| Operating Labor (\$/yr) | \$ | 775,000 | \$ | 775,000 |
| Raw Materials (\$/yr) | \$ | 87,000,000 | \$ | 87,000,000 |
| Utilities (\$/yr) | \$ | 1,600,000 | \$ | 2,600,000 |
| Wastewater Treatment (\$/yr) | \$ | 570 | \$ | 560 |
| Annual Production Cost (\$/yr) | \$ | 89,300,000 | \$ | 90,400,000 |
| Unit Production Cost (\$/lb $\mathbf{m}_{\mathbf{m}}$ ) | \$ | 1.05 | \$ | 1.06 |

Figure 49: Production Cost Summary

The revenue was estimated using a production rate of $85,000,000 \mathrm{lbm} / \mathrm{yr}$ and $\$ 1.45 / \mathrm{lbm}$ for nylon 6,6 [29]. The annual revenue for the plant is estimated to be $\$ 123,250,000$.

An incremental NPV analysis was completed to compare the Batch/CSTR and PFR/CSTR options at each specified production capacity, $100 \%$ and $67 \%$. The incremental analysis was done by subtracting $\mathrm{NPV}_{\text {PFR/CSTR }}$ from $\mathrm{NPV}_{\text {Batch/CSTR. }}$. The results of the incremental analysis indicate that the Batch/CSTR process is more economically attractive. Figure 50 displays the results of the incremental analysis at $100 \%$ capacity, and the results for $67 \%$ are shown in Figure 51.

| Incremental Analysis - 100\% |  |  |
| :--- | :--- | :--- |
| $\mathrm{NPV}_{\text {Batch/CSTR }}$ | $\$$ | $73,360,000$ |
| $\mathrm{NPV}_{\text {PFR/CSTR }}$ | $\$$ | $70,660,000$ |
| $\mathrm{NPV}_{\text {Batch-PFR }}$ | $\$$ | $\$ 2,700,000$ |

Figure 50: 100 \% Capacity Incremental Analysis

| Incremental Analysis - 67\% |  |  |
| :--- | :--- | :---: |
| NPV $_{\text {Batch/CSTR }}$ | $\$$ | $48,270,000$ |
| NPV $_{\text {PFR/CSTR }}$ | $\$$ | $45,680,000$ |
| NPV $_{\text {Batch-PFR }}$ | $\$$ | $2,590,000$ |

Figure 51: Turndown Incremental Analysis

The DCFROR for each case was also considered when comparing the two processes. The results of DCFROR calculations are summarized below in Figure 52.

| DCFROR |  |  |
| :---: | :---: | :---: |
|  | Batch/CSTR | PFR/CSTR |
| $100 \%$ | $5.17 \%$ | $4.11 \%$ |
| $67 \%$ | $4.86 \%$ | $2.69 \%$ |

Figure 52: DCFROR Summary

Once the Batch/CSTR option was chosen, a sensitivity analysis was performed to evaluate the effect of various changes on the overall economics of the project. In this analysis, each factor was varied by $\pm 15 \%$. Of the variables considered, the sale price of nylon 6,6 had the largest economic impact, while utility and labor costs had very low impacts. Figure 53, below, displays the results of the sensitivity analysis on the Batch/CSTR process.

Figure 53: Sensitivity Analysis

## Conclusions and Recommendations

The preliminary design assembled in this report produces the necessary $85 \mathrm{MM} \mathrm{lbm} / \mathrm{yr}$ of nylon 6,6 , and does so while producing a high profit margin. An economic analysis over a 10 year time period was completed on Page 64 , and shows that the net present value for this design is $\$ 73,360,000$ and the DCFROR is $5.17 \%$. This design presents a hazard operability study on Page 50 It is recommended that these analyses be completed in even more detail for the detailed design in order to maximize safety.

Total capital costs, including the grassroots factor, are $\$ 4.03$ million, and are summarized on Page 45. Total manufacturing costs, including raw materials, are $\$ 89.3$ million per year, and are given in more detail on Page 61. At the current estimated prices for nylon 6,6 , this process will produce approximately $\$ 123.3$ million in annual revenue in today's dollars. A summary list of equipment is given on Page 22.

This design made a number of assumptions that will need to be validated before proceeding. Most of these are involved in costing, and thus the design team recommends completing a more thorough costing analysis. Several assumptions and heuristics were used in the design of the process equipment. These range from area or volume calculations to how the equipment or reaction will behave. These heuristics will need to be validated, and the design team recommends a more thorough investigation into how the reaction and process equipment will behave under the specified conditions. In conclusion, the design team recommends that upper management proceed with a detailed design of the preliminary design provided in this report.

## Acknowledgements

The design team would like to acknowledge and thank Mr. Roger Colburn, General Manager of Calvert City Water and Sewer, and Dr. Ben D. Herzog, Vice President of Innovation, Technology and Intellectual Property for Invista. Mr. Colburn was very helpful with providing industrial water rates to help ensure that the water utility costs were as accurate as possible. Dr. Herzog also provided raw material costs for ADA and HDMA.
